GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index, is \$90.00 U.S., Canada and Mexico and \$120.00 foreign. Individual issues will be charged at \$10.00 to subscribers, \$15.00 each to non-subscribers. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

REVIEW

- 79-2401 **Somatic Mosaicism in Plants with Special Reference to Somatic Crossing Over.** (Eng) Vig, B. K. (Dept. Biology, Univ. Nevada at Reno, Reno, NV 89557) *Environ Health Perspect* 27: 27-36; 1978.

The use of somatic mosaicism induction in plants as a tool in the study of environmental mutagenesis was evaluated. Higher plant systems that are promising for the study of mutagen-induced mosaicism include *Tradescantia hirsuticaulis*, *Glycine max*, *Antirrhinum majus*, *Pisum sativum*, *Nicotiana tabacum*, *Zea mays*, and *Arabidopsis thaliana*. As an example of the nature of mosaicism, the soybean system is described in detail. The gene combination of $Y_{11}y_{11}$ has been used as a marker system in this species. Various mutagens may result in mosaicism, which may consist of dark green, yellow, or twin (double) spots on the two simple leaves. The twin spots are inferred to originate by somatic crossing over. Some of the single spots may occur as a result of the failure of one component of twin spots; others may be caused by chromosomal segmental losses or numerical inequalities in chromosome distribution during mitosis. Twin spots occur in other species, and they can be induced by caffeine administration. Studies of mosaicism in plants offer inexpensive, rapid, and reliable tests of mutagenicity, at least as preliminary eukaryotic test systems. (47 refs)

- 79-2402 **Literature Survey of Bacterial, Fungal, and *Drosophila* Assay Systems Used in the Evaluation of Selected Chemical Compounds for Mutagenic Activity.** (Eng) Brown, M. M. (Environmental Mutagen Information Center, Information Center Complex Information Div., Oak Ridge Natl. Lab., P.O. Box Y, Building 9221, Oak Ridge, TN 37830); Wassom, J. S.; Malling, H. V.; Shelby, M. D.; Von Halle, E. S. *J Natl Cancer Inst* 62(4): 841-871; 1979.

Literature data on the use of seven nonmammalian assay systems for the detection of mutagenicity or other related genetic effects are reviewed. The activities of 54 selected noncarcinogens, procarcinogens, and ultimate carcinogens as revealed by these test systems were compared. Forty-nine of the compounds tested were active in one or more of the assays, and 42 were positive in at least one system without metabolic activation. In one or more test systems, 17/17 ultimate carcinogens, 27/28 procarcinogens, and 6/9 noncarcinogens were positive. The Ames Salmonella-microsome assay responded with increased mutation frequency to 37/44 carcinogens but to only 2/8 noncarcinogens tested. The *Drosophila* system responded to 19/21 carcinogens and to 3/6 noncarcinogens tested. Pro-

phages were induced when lysogenic bacteria were exposed to 12/21 carcinogens, but not enough tests were done with the noncarcinogens (1/3) for a comparison. The other systems reviewed, such as the killing of repair-deficient bacteria, mutations in *Escherichia coli* and *Neurospora crassa*, and the host-mediated assay, were not challenged by enough of the compounds for valid comparisons. (439 refs)

- 79-2403 **A Strategy Using Short-Term Assays to Identify Carcinogens That Act in Man.** (Eng) Bruce, W. R. (Ontario Cancer Inst., 500 Sherbourne St., Toronto M4X 1K9, Ontario, Canada); Dion, P. D.; Kakizoe, T.; Land, P. C. *Nutr and Cancer* 1(2): 4-7; 1979.

A scheme is presented for the use of short-term tests to identify carcinogens that act in humans, and it is illustrated by applications to colon and bladder cancer. Short-term tests can be used to determine if there is a measurable level of presumed carcinogen in individuals at risk for the disease. If the presumed carcinogen(s) appears to associate with specific cancers, then it is possible that the chemical detected by the assay is responsible for the cancer. The shorter-term tests can also be used to determine the nature and structure of the presumed carcinogen. This procedure involves chemically purifying the agent detected by the assay and identifying its structure. These steps are followed by basic studies of the origin of the presumed carcinogen and confirmation of its carcinogenicity in animal tests. The scheme also involves inhibition of or reduction of exposure to the presumed carcinogen in vivo, intervention in high-risk patients, and intervention in normal populations. Because the short-term assays are cheap, they should be used in the initial investigations to search for possible problems and to define areas of concern. Because they are not always accurate, they must be supported by systematic animal studies. (19 refs)

- 79-2404 **A Review of the Metabolism of Xenobiotics by Microorganisms with Relation to Short-Term Test Systems for Environmental Carcinogens.** (Eng) Callen, D. F. (Flinders Univ. South Australia, Bedford Park, S.A. 5042, Australia) *Mutat Res* 55(3/4): 153-163; 1978.

Aspects of the metabolism of xenobiotics by microorganisms that are relevant to short-term test systems for environmental carcinogens are reviewed. The presence of a cytochrome P-450-dependent monooxygenase system

has been established in a variety of fungi and bacteria. The cytochrome P-450-dependent monooxygenase system of fungi is similar to that of mammals, but some differences are apparent. The bacterial enzyme system consists of a soluble cytochrome P-450 with a requirement for NADH. A microbial test system in which activation is possible within the microbial cells may be a more adequate model of the in vivo situation than the activation systems now in use. A disadvantage of these systems is that a carcinogen may be metabolized in microorganisms by pathways that differ from those of mammals. Mammalian intestinal microbial flora have a role in the etiology of colon and rectal cancer, which should be recognized in microbial test systems for environmental carcinogens. A number of hydroxy-anthraquinones that were nonmutagenic in the Ames *Salmonella* assay were mutagenic when the liver homogenate used in the assay was replaced by a cell-free extract of intestinal microflora. It is suggested that gut microflora should be incorporated in short-term screening tests. (83 refs)

- 79-2405 Data on Environmental Carcinogenic Polycyclic Aromatic Hydrocarbons. (Hun) Shabad, L. M. (Oncology Res. Center, USSR Acad. Medical Sciences, Moscow, USSR) *Magy Onkol* 23(1): 3-11; 1979.

Studies of the general environmental problems of carcinogenic polycyclic aromatic hydrocarbons (PAH's) are reviewed. In view of the good correlation between concentrations of benzo(a)pyrene and other PAH's, the former can be used as an indicator of overall PAH levels. PAH's are generated during combustion processes and also by plants (eg, during germination). They accumulate in soil and bodies of water, and they are partially decomposed by certain microorganisms; but a background level persists. Similar tumor induction rates were observed in mice following topical application of pure benzo(a)pyrene and of soot extracted from automotive exhaust gases. (no refs)

- 79-2406 Clinical Practice and Epidemiology: Two Worlds or One? (Eng) Acheson, E. D. (Univ. Dept. Community Medicine, General Hosp., Southampton SO9 4XY, England) *Br Med J* 1(6165): 723-726; 1979.

The relationship between epidemiology and clinical medicine is discussed, particularly with regard to the study of various suspected carcinogens. (13 refs)

- 79-2407 Environmental Carcinogenesis--Part II. (Eng) Hadden, J. W. (Dept. Medicine, Sloan-Kettering Inst. Cancer Res., New York, NY) *Clin Bull* 8(4): 164-167; 1978.

Several carcinogenesis research projects of the Sloan-Kettering Institute (New York, NY) are reviewed. The induction of rat tumors by methylazoxymethanol (MAM) acetate is being used as a model for human colon cancer. These studies suggest that the effects of the carcinogen are due to a metabolite resulting from a dehydrogenase reaction. In humans and rodents with a genetic predisposition to colon, stomach, and cervical cancer, abnormal proliferative activity can be detected in the cells even before the subjects develop neoplastic lesions. A study is in progress to quantitate the development of abnormally proliferative gastrointestinal cells in several high-risk population groups as an early indication of susceptibility to neoplasia. Cloned lines of epithelial liver cells from rats sacrificed after po administration of diethylnitrosamine contained juxtanuclear filamentous aggregates resembling the Mallory bodies (alcoholic hyaline) frequently seen in cirrhotic livers of chronic alcoholics. These heritably maintained cytoplasmic structures are the result of an impairment of microtubule formation and function, an abnormal accumulation of intermediate filaments, and modulation of cell membrane receptors. Other studies are focusing on the theory that diol epoxides are the ultimate carcinogens of polycyclic hydrocarbons, on the interaction of adriamycin with DNA, on changes produced in transfer RNA's of target organs by carcinogens, and on whether in vitro screening tests for transformation and mutagenesis have predictive value for detection of carcinogenic activity. (no refs)

- 79-2408 Saccharin: From Carcinogen to Promoter. (Eng) Boyland, E. (London Sch. Hygiene and Tropical Medicine, London, England) *Nature* 278(5700): 123-124; 1979.

Evidence that saccharin may be a promoting agent rather than a complete carcinogen is reviewed. In eight studies in which saccharin was fed to rats, the bladder tumor incidence was never more than 44% and was usually lower, even when the diets contained 5% saccharin. When small initiating doses of methyl nitrosourea were instilled into the urinary bladder of Wistar rats, no bladder tumors were detected. Of the rats that were subsequently given saccharin in drinking water, 57% developed tumors. Similar results were obtained when rats were fed 2% N-(4-(5-nitro-2-furyl)-2-thiazolyl)formamide (FANF) followed by 5% saccharin. Cultures of C3H/10T1/2 cells treated with non-transforming initiating doses of methylcholanthrene + saccharin had a statistically significant number of transformations. These experiments indicate that saccharin is a promoter rather than a direct carcinogen. Although saccharin may not be harmless, it is unlikely to be a serious hazard because the dose required to produce the promoting effect is so large (1 kg/kg body wt). (18 refs)

- 79-2409 Azide. (Eng) Kleinhofs, A. (Program in Genetics, Washington State Univ., Pullman,

WA 99164); Owais, W. M.; Nilan, R. A. *Mutat Res* 55(3/4): 165-195; 1978.

The mutagenic and toxicological properties of sodium and potassium azides are reviewed. Most of the physiological and toxicological properties of azide can be traced to its inhibition of enzymes containing a coordinated divalent metal ion. The potent mutagenicity of azide has been recognized only recently; this mutagenicity is highly dependent on a defective excision-repair system and a functional recombination system. Azide mutagenesis is very specific in that it is unable to revert any of the frameshift, *ochre*, or *amber Salmonella typhimurium* mutants so far tested. There is little or no relationship between the mutagenic properties of azide and its properties as a respiration and catalase/peroxidase inhibitor. Sodium azide was not mutagenic in *Drosophila*, but it induced mutations in Chinese hamster cell lines. The mono- and di-azido derivatives of ethidium bromide were highly mutagenic in yeast and in *S. typhimurium*. Azide analogs of proflavine and acriflavine induced high frequencies of frameshift mutations in excision-repair *Salmonella* strains. Sodium azide was not carcinogenic in male or female rats given the max tolerated dose or half that level in the diet 2x/wk. The mutagenic action of sodium azide in barley is of concern because of the danger of introducing stable mutagens into the food chain. (226 refs)

79-2410 Chloroprene (2-Chloro-1,3-butadiene)--What Is the Evidence for Its Carcinogenicity? (Eng)

Haley, T. J. (Dept. Health, Education, and Welfare, Food and Drug Admin., Natl. Center Toxicological Res., Jefferson, AR 72079) *Clin Toxicol* 13(2): 153-170; 1978.

The biochemistry, metabolism, and toxicology of chloroprene (CP: 2-chloro-1,3-butadiene) were reevaluated to establish whether it is a potential carcinogen. The LD_{50} 's of CP in mice and rats are 260 and 251 mg/kg, respectively. The pathologic changes in these animals included hemorrhages and dystrophic changes in the CNS, lungs, kidneys, and spleen. Chronic inhalation of CP by dogs resulted in changes in higher nervous activity, the nerve cells of the cerebral cortex, and the brain vasculature. Blood histamine increased and histaminase activity decreased in 103 Soviet workers exposed to CP, and the changes were related to duration of exposure. During chronic CP intoxication, there was dysfunction of both the CNS and peripheral nervous system, particularly the cholinergic branch. Cytogenetic analysis of somatic cells from exposed workers aged 23-59 yr revealed both chromosome and chromatid aberrations. Immunization of 208 CP workers with typhoid vaccine produced low immunologic reactivity and no increase in phagocytic activity. In mice, the growth of transplanted Crocker's sarcoma was accelerated by sc CP injection. During 1956-1970, 137 cases of skin cancer were diagnosed in 24,989 Soviet patients; CP workers had the highest skin cancer incidence (21/684),

followed by persons working with CP derivatives (38/2,250). In the same period, 87 lung cancers were found in 19,979 workers; 18 of the patients had direct and prolonged exposure to CP and 16 had a history of exposure to CP latexes. Worldwide epidemiology studies should be undertaken to validate the Soviet reports of CP carcinogenicity in humans. Additional metabolic studies are also necessary to define the neurohumoral mechanism of CP action. (149 refs)

79-2411 Carcinogenicity of Phenacetin (2 Letters to Editor). (Eng) Tomatis, L. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, World Health Organization, 69372, Lyon Cedex 2, France); Johansson, S.; Angervall, L. *Science* 204(4389): 129-130; 1979.

Some recently published results of clinical, epidemiologic, and experimental studies of the possible carcinogenicity of phenacetin (PA) and PA-containing compounds are cited in two letters. These studies were not mentioned in a previous letter in which a study demonstrating that PA was not carcinogenic in rats was quoted. However, other studies have shown that PA and N-hydroxyphenacetin cause urinary tract and nasal cavity tumors in rats. In addition, epidemiologic studies have shown an association between PA abuse and the development of renal pelvic, bladder, and ureteral tumors. (17 refs)

79-2412 The Carcinogenicity of Kepone. (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD 21701) *J Environ Pathol Toxicol* 2(3): 671-686; 1979.

All known animal studies of the carcinogenicity of the chlorinated pesticide decachlorooctahydro-1,3,4-metheno-2H-cyclobuta(cd)pentalen-2-one (Kepone) are reviewed. Kepone induced malignant liver tumors in rats and mice fed the chemical in the diet. Malignant tumors were also found in organs other than the liver in rats, and these were induced even by the lowest dose administered. Female rats were more susceptible to the development of malignant tumors than male rats. Kepone also induced toxic changes, particularly in male rats, and they included renal interstitial fibrosis, testicular atrophy, and polyarteritis of the mesenteric, pancreatic, and other arteries. (7 refs)

79-2413 Environmental Pollutants and the Epidemiology of Cancer. (Eng) Health, C. W. (Chronic Diseases Div., Bureau Epidemiology, Center Disease Control, Atlanta, GA 30333) *Environ Health Perspect* 27: 7-10; 1978.

Approaches used in epidemiologic studies of environmental carcinogenesis are reviewed briefly. Some approaches, as with kepone, a chlorinated hydrocarbon insecticide, and with polybrominated biphenyls, start with exposed populations and measure disease frequency, the so-called prospective or cohort approach. Others, illustrated by vinyl chloride monomer studies, start with cases of cancer (hepatic angiosarcoma) and measure the extent of toxic exposure; ie, the retrospective or case history (case-control) approach. Other studies describe patterns of cancer occurrence and then seek correlations with potentially related population characteristics. All of these approaches are part of epidemiologic methodology and all are predicated on the existence of prior human exposure or prior disease occurrence. In this regard, major limiting factors involve concepts of latency and exposure dose. Although in vitro and animal test systems will never fully supplant human studies, they represent the only means for detecting potential carcinogenicity before human exposure has become widespread or long-established. (17 refs)

- 79-2414 **Hazards Associated with Exposure to Vinyl Chloride and Polyvinyl Chloride Materials.** (Rus) Diubankova, E. N. (F. F. Erisman Res. Inst. Hygiene, Moscow, USSR); Bykhovskii, A. V. *Gig Sanit* (1): 69-74; 1979.

Current data on the hazards of vinyl chloride (VC), in general, and of the use of polyvinyl chloride packages, in particular, are reviewed. Seventeen cases of liver angiosarcoma have been reported in workers in the VC industry (compared with the total 45 cases reported in the world literature). In addition to liver angiosarcomas, the workers had an increased incidence of cancer of the respiratory, CNS, lymph, and hematopoietic systems. The long-term storage of alcohol in PVC bottles showed distinct organoleptic changes in the alcohol that prompted a ban on the use of PVC containers for food products containing alcohol. (26 refs)

- 79-2415 **Vinyl Halides: Carcinogenicity. Vinyl Bromide, Vinyl Chloride, and Vinylidene Chloride.** (Eng) Bahlman, L. J. (Natl. Inst. Occupational Safety and Health, 5600 Fishers Lane, Rockville, MD 20857); Alexander, V.; Infante, P. F.; Wagoner, J. K.; Lane, J. M.; Bingham, E. *Am Ind Hyg Assoc J* 40(4): A-30-A-40; 1979.

Laboratory studies demonstrating the carcinogenicity and mutagenicity of vinyl chloride (VC), vinylidene chloride (VDC), and vinyl bromide (VB) are reviewed, together with studies demonstrating the carcinogenicity and mutagenicity of VC in humans. Liver angiosarcomas have been induced in rats or mice by vinyl halide concentrations of 25-55 ppm. It is recommended that VB and VDC be considered in the

workplace as potential carcinogens to humans and controlled with the same degree of prudence as VC. (35 refs)

- 79-2416 **Some Comments on the History and Experimental Explorations of Metal Carcinogens and Cancers.** (Eng) Hueper, W. C. (Journal of the Natl. Cancer Inst., Room 2A01, Blair Building, Bethesda, MD 20014) *J Natl Cancer Inst* 62(4): 723-725; 1979.

The historical background and studies of metal carcinogens and metal-induced cancers are reviewed. Around 1935, cancers of the lung were discovered in chromate workers and cancers of the lung and nasal sinuses were found in nickel refiners. Since then, beryllium, cadmium, cobalt, lead, selenium, mercury, gold, and zinc have been identified as carcinogens, and iron has been suggested as a possible carcinogen. Because of their extensive use in industry and consumer goods, the importance of chromates and Ni as environmental carcinogens has increased. Animal experiments have firmly established the carcinogenicity of chromium when it is introduced in a biologically available form that permits interaction between the carcinogen and tissue. Both epidemiologic evidence and animal experiments have also demonstrated the carcinogenicity of Ni compounds and metallic Ni. Large granulomas, but not cancers, resulted when powdered Fe was injected into the pleura or lungs of rats, and osteogenic sarcomas resulted when uranium was injected into the marrow cavities of rat femurs. Whether the latter cancers were caused by radiation or the metal itself is not certain. (no refs)

- 79-2417 **Pesticide Use in Agriculture.** (Eng) Ridgway, R. L. (Science and Education Admin., U.S. Dept. Agriculture, Beltsville, MD 20705); Tinney, J. C.; MacGregor, J. T.; Starler, N. J. *Environ Health Perspect* 27: 103-112; 1978.

Quantitation of mutagenic and carcinogenic risks from pesticide use in agriculture is important because of recent reports that representatives of the major classes of pesticides are suspect mutagens and/or carcinogens. These classes include triazines, organochlorines, carbamates, dithiocarbamates, organophosphates, phthalimides, amides, phenyl ureas, phenoxyacetic acids, and benzimidazoles, >80% of all synthetic organic pesticides now used in the US. Regulatory decisions will be a major determinant of future pesticide technology. Evaluation of laboratory findings in terms of risk is often impossible if the mechanisms by which genetic damage arises are unknown. For example, interpretation of the finding that certain herbicides cause structural abnormalities in plant chromosomes would be quite different if the effect resulted from direct alkylation of DNA rather than, as has been suggested, as a secondary effect of severe physiological

disturbances in the plant. Higher plants have potential use as monitors of mutagens in the environment. For example, monitoring the frequency of atrazine-induced mutations in field plants revealed a mutagenic effect due to environmental conversion products that might not have been appreciated from conventional laboratory tests of the pesticide per se or from chemical determinations of atrazine residues in the field. Hopefully, the integration of monitoring data with laboratory and epidemiological data will result in a quantitative measure of health risk. The use of benefit-cost (risk) analyses in regulatory decision-making processes is also surveyed. (46 refs)

- 79-2418 **Activation of Chemicals into Mutagens by Green Plants: A Preliminary Discussion.** (Eng) Plewa, M. J. (Inst. Environmental Studies, Univ. Illinois, Urbana, IL 61801) *Environ Health Perspect* 27: 45-50; 1978.

Recent studies that demonstrate the activation of chemicals, particularly pesticides, into mutagens by green plants are reviewed. Three techniques are involved in research on plant activation. In the in vitro method, growing plants are exposed to a suspect chemical, the plant tissues are homogenized, and microbial indicator organisms are exposed to an extract made from the treated plants. The in vitro method involves incubating a test chemical with an untreated plant homogenate supplemented with cofactors and assaying the homogenate by microbial indicator organisms. The genetic endpoint of the in situ method is reversion at the *waxy* (*wx*) locus of *Zea mays* maize microgametophytes (pollen grains). The history and results of several studies with this method are described. Although it does not have the controlled laboratory conditions of the in vivo and in vitro methods, it does detect the presence of a mutagen within the ecological dynamics of the agricultural field. Results of screening some pesticides and combinations of pesticides with the maize *wx* locus assay are tabulated. The s-triazine herbicides have been chosen for studies in plant activation because of their wide-spread use in agriculture and the contradictory results concerning their mutagenicity. The results of various assays indicate that the s-triazine herbicides atrazine, simazine, and cyanazine induce both mitotic and meiotic chromosome aberrations and that they are activated biologically into agents that induce point mutations. (54 refs)

- 79-2419 **Role of pH in Chemical Mutagenesis.** (Eng) Singh, C. (Regional Res. Lab., Jammu Tawi, India); Kaul, B. L. *J Sci Ind Res* 37(8): 426-432; 1978.

Studies of the effect of pH on chemical mutagenicity are reviewed. Although there are contradictory reports, in general, ethylmethane sulfonate- and diethyl sulfate-

induced mutagenic activities increase at low pH and are almost similar. They may differ quantitatively, however, depending on the concentration of the mutagen used and its hydrolysis rate. Isopropylmethane sulfonate, β -propiolactone, and 1,3-propane sultone are largely unaffected by pH changes. Nitroso compounds also have increased activity at acidic pH, and they show a correlation between mutagenicity and decomposition rate. Mutagenicity is increased if the nitroso compounds, eg, N-methyl-N-nitrosourea, N-ethyl-N-nitrosourea, and N,N-dimethyl-N-nitrosourea, are administered at a pH range in which the half-life of the mutagen exceeds the duration of treatment. Aliphatic nitrogen mustards [N-ethylbis-(β -chloroethyl)amine hydrochloride and N-methylbis-(β -chloroethyl)amine hydrochloride] and ethylenimine have increased mutagenic activity under alkaline conditions. - 79-2420 **An Evaluation of Systemic Tumorigenesis Following Topical Application of Chemicals (Meeting Abstract).** (Eng) Tobin, P. (Div. Toxicology, Food and Drug Admin., Washington, DC); Kornhauser, A.; Scheuplein, R. *Clin Res* 27(2): 537A; 1979 (no refs)

- 79-2421 **Glycolipids and Malignancy: A Review of Some Current Ideas (Meeting Abstract).** (Eng) Critchley, D. R. (Dept. Biochemistry, Univ. Leicester, Leicester, England) *Br J Cancer* 39(4): 460-462; 1979 (29 refs)

- 79-2422 **Prostaglandins and Drug Induced Agranulocytosis, Aplastic Anaemia and Leukemia.** (Eng) Das, U. N. (Dept. Genetics, Osmania Univ., Hyderabad-500007, India) *Prostaglandins Med* 2(3): 235-238; 1979.

The relationship between drug-induced agranulocytosis (AGC), aplastic anemia (AA), and leukemia and the effects of the drugs on the prostaglandin system are considered. Drugs such as aspirin, indomethacin, phenylbutazone, chloroquine, and quinine have been reported to induce, or at least are associated with, AA, AGC, and, occasionally, leukemia. Cyclic AMP and cyclic guanosine monophosphate (GMP) may regulate the proliferation and differentiation of granulocyte-macrophage progenitor cells. Since prostaglandins influence intracellular cyclic AMP and cyclic GMP levels, drugs that affect the synthesis or action of prostaglandins could indirectly influence the levels of these two nucleotides and thus cause AGC and AA. Some cases of leukemia have been reported in chloroquine-induced AA and AGC. Leukemic cells have a low phagocytic index, low chemotacticity, and low levels of cyclic AMP, parameters influenced by prostaglandins. A

chloroquine-induced decrease in prostaglandin activity may be responsible for the malignant transformation of WBC. This hypothesis is supported by the fact that prostaglandin E can block tumor development in animals and in vitro. In addition, treatment of malaria by chloroquine may be a factor in the pathogenesis of Burkitt's lymphoma. It is proposed, therefore, that drugs that interfere with the prostaglandin system can induce AGC, AA, and leukemia. (22 refs)

- 79-2423 Toxicity of Chloramphenicol and Thiamphenicol (CAP and TAP). (Ger) Keiser, G. (Medizinische Abteilung, Burgerspital, 6300 Zug, Switzerland) *Haematol Bluttransfus* 21: 179-195; 1978.

The bacteriostatic action of chloramphenicol (CAP) and thiamphenicol (TAP) and their early and late toxic effects on mammalian cells, including the occurrence of aplastic anemia and leukemia in humans, are reviewed. CAP has an -NO₂ group in the para- position, TAP a -CH₃SO₂ group. Under the same conditions, the covalent binding of CAP to liver and bone marrow mitochondria is 12 times greater than that of TAP. At therapeutic doses, CAP inhibits DNA synthesis in animal erythroblast cultures, but TAP does not. Thus, CAP has two effects that are characteristic of toxic or mutagenic substances. CAP, but not TAP, leads to irreversible bone marrow damage and thus to aplastic anemia. CAP is the drug most commonly implicated in aplastic anemia cases associated with chemicals (312 cases vs 35 for phenylbutazone, the second most commonly implicated drug). Thirty cases of leukemia after CAP use are described in the literature; 15 are described in detail, and an effect of CAP seems probable in these cases. The therapeutic use of CAP is not justified in view of these findings. In contrast, TAP appears to be a useful antibiotic and cytostatic agent, particularly for polycythemia. (39 refs)

- 79-2424 Vitamin A and Cancer of Epithelial Origin. (Eng) Basu, T. K. (Div. Nutrition, Dept. Biochemistry, Univ. Surrey, Guildford, Surrey, England) *J Hum Nutr* 33(1): 24-31; 1979.

The role of vitamin A in protecting against and treating cancers of epithelial origin is reviewed. Vitamin A has been shown to protect against squamous metaplasia in experimental animals exposed to carcinogenic polycyclic aromatic hydrocarbons (PAH). In humans, low plasma vitamin A and β -carotene levels have been associated with squamous cell carcinomas of the bronchi, oral cavity, and oropharynx. A wealth of experimental evidence from animal studies suggests that supplementary feeding of vitamin A and retinoic acid can induce cellular repair of pathologic changes by PAH. The incidence of carcinoma in hamsters treated with benzo(a)pyrene was drastically in-

hibited when the animals were placed on lifetime po treatment with 13-cis-retinoic acid following completion of carcinogen dosing. No deleterious side effects were noted with retinoid doses as high as 9 mg/wk, although even one-half as much retinyl acetate or all-trans-retinoic acid would have been severely toxic. 13-cis-Retinoic acid has also been reported to have a marked inhibitory effect on bladder cancers induced in rats by N-methyl-N-nitrosourea. Thus, vitamin A appears to have prophylactic as well as therapeutic activity against certain cancers, and the use of vitamin A analogs may reduce toxicity. (39 refs)

- 79-2425 The Epidemiology of Cancer of the Oesophagus. (Eng) Cook-Mozaffari, P. (Medical Res. Council External Staff, Dept. Regius Professor Medicine, Univ. Oxford, Oxford OX1 3QG, England) *Nutr and Cancer* 1(2): 51-60; 1979.

The epidemiology of esophageal cancer (EC) is reviewed. The range of incidence between different regions varies 500-fold. Sharp gradients of incidence occur between regions only a few hundred miles apart. High-incidence areas (HIA's) have been found in Iran and in southern and eastern Africa. Sometimes the rates for women show the same high frequency as those for men, but often they occur at a much lower level. In the HIA's of Normandy and Brittany, the male:female ratio is >25:1. Clear but small-scale increases in incidence have been recorded for both sexes among US Blacks and for men in northern France. During the last 30-40 yr, EC has become one of the commonest types of cancer diagnosed in southern Africa; previously, it was nonexistent. In the HIA of Iran, however, the disease was described as long ago as the 12th century. In several HIA's vitamin A and riboflavin deficiencies appear to be associated with EC. In Kenya and other parts of Africa, there is some evidence to implicate home-brewed beer made from maize. A case-control study in Normandy and Brittany indicated that most of the excess risk for EC could be ascribed to a multiplicative effect of drinking and smoking. However, the sum of these various factors is not sufficient to account for the exceptionally high incidences and extraordinary pattern of variation of EC. (59 refs)

- 79-2426 Effects of Hair Sprays Need Investigation (Letter to Editor). (Eng) McInnes, B. (140 Dubois Ave., Valley Stream, NY 11581) *N Engl J Med* 300(15): 863; 1979.

The importance of investigating the possible relationship between the use of hair sprays and lung cancer is pointed out. One study, which did not control for cigarette smoking, demonstrated that the risk of lung cancer among female beauticians was 6.92 times greater than that among nonbeauticians; however, the study focused on contact with hair dyes, and sprays were not mentioned. (1 ref)

79-2427 Cigarette Smoke-induced Laryngeal Cancer: A Model for Bronchogenic Carcinoma in Humans (Letter to Editor). (Eng) Homburger, F. (Boston Univ. Sch. Medicine, Boston, MA 02118); Bernfeld, P. *N Engl J Med* 300(15): 862; 1979.

In a critique of the Surgeon General's report on smoking and health, it is pointed out that carcinogenesis using tar fractions or smoke inhalation has not been successful in the respiratory tract of small animals, except for the induction of laryngeal cancer in certain susceptible inbred Syrian hamster strains. In addition, in these hamsters, it is presently possible to determine at least whether low-tar cigarettes are more or less carcinogenic than high-tar cigarettes. (9 refs)

79-2428 Oral Contraceptives and Liver Tumours (Letter to Editor). (Eng) Gray, R. H. (World Health Organization, 1211 Geneva 27, Switzerland) *Med J Aust* 2(11): 531; 1978.

Conclusions of a World Health Organization study of the risk of liver neoplasia associated with the use of oral contraceptives (OC), especially those containing high doses of steroids, are summarized. There is a marked increase in the relative risk of hepatocellular adenoma (HCA) among women who have used OC for >3 yr. The magnitude of risk increases with dose of steroid, duration of use, and age of user. However, preliminary calculations suggest that the attributable risk of HCA among women <30 yr old is no more than 3/100,000 users per year, regardless of length of use. This risk is higher for women >30 yr old. (4 refs)

79-2429 Features of Liver Damage due to 17 α -Alkyl-substituted Anabolic Steroids. (Ita) Lovisetto, P. (Istituto di Medicina Interna, Università di Torino, Turin, Italy); Mairano, D.; Actis, G. C.; Marchi, L. *Minerva Med* 70(11): 769-790; 1979.

Studies of liver damage (intrahepatic cholestasis, hepatic peliosis, and tumors) caused by 17 α -alkyl-substituted steroids are reviewed. Liver tumors induced by these steroids are very similar to those induced by estrogens and progestins. The 17 α -alkylation is believed to lead to proliferation of the hepatic parenchyma. The anatomical picture resembles that of benign adenoma, hepatocarcinoma, and widespread multinodular hyperplasia. There is a marked discrepancy between histological type and clinical course: some tumors rated as carcinomas regress completely on suspension of the steroid treatment. The term tumor is thus inappropriate: these lesions can best be described as hormone-dependent, histopathologically unusual proliferative alterations. Liver tumors reported in the literature occurred following treatment with testosterone (50 mg/day for 4 mo), oxymetholone (30-300 mg/day for

3-50 mo), methyltestosterone (20-50 mg/day for 40 mo-30 yr), and methandrostenolone (15 mg/day for 89 mo). (57 refs)

79-2430 Essential Hormones as Carcinogenic Hazards. (Eng) Hickey, R. J. (Wharton Sch., Univ. Pennsylvania, Philadelphia, PA 19104); Clelland, R. C.; Bowers, E. J. *J Occup Med* 21(4): 265-268; 1979.

The inclusion of some endocrine biochemicals on a list [published by the Occupational Safety and Health Administration (OSHA)] of environmental substances that pose a potential occupational carcinogenic risk is critically evaluated. At appropriate levels, these substances are essential for proper physiological functioning both in humans and other mammals. These substances include estradiol, estrone, estriol, progesterone, and testosterone. Review of some of the evidence implicating steroidal hormones as carcinogens indicates that estradiol and progesterone may promote the growth of mammary tumors previously initiated by true carcinogens, but that they themselves are not carcinogens. Estrogens and androgens are used in the treatment of some mammary carcinomas. Other substances on the OSHA list include tannic acid and tannins (which are present in tea), maltose, and lactose, a normal ingredient at appreciable concentration in human and other mammalian milks. It is concluded that a major reappraisal of the OSHA list is essential. (22 refs)

79-2431 Hormones and Mammary Carcinogenesis. (Eng) Segaloff, A. (Section Endocrine Res., Richard W. Freeman Res. Inst., Alton Ochsner Medical Foundation, 1516 Jefferson Highway, New Orleans, LA 70121) *Breast Cancer 2. Additives in Research and Treatment.* McGuire, W. L., ed. (New York: Plenum Medical Book Company): 407 pp.; 1-22; 1978.

Studies of hormones and their association with mammary cancer are reviewed, with emphasis on studies in the rat. Mammary carcinogenesis can be induced in intact A x C female rats by the continuous administration of estrogen. This strain is probably the one most consistently susceptible to estrogen induction of mammary gland cancers. Oophorectomized rats are not as sensitive to the effects of estrogen as intact animals, even when progesterone is replaced by pellets or injections. Studies of the various other substances from the ovary that might explain these results led to the hypothesis that relaxin is the ovarian nonsteroidal substance required for the greatest carcinogenesis. Estrogen seems to provide the substrate for carcinogenesis in animals that already have a genetic or other means of initiation. Thyroid substance does not seem to be related to breast cancer, except as its level in the host has an effect on the biotransformation of estrogens. Continuous estrogen action on the mammary gland seems to be

required for a prolonged period of time and in an appropriate amount for each animal species for mammary carcinogenesis. Insulin is probably required for mammary carcinogenesis, at least for promotion to identifiable clinical size. Studies of the effects of progesterone and pituitary hormones have produced conflicting results. In rats, pituitary hormones are apparently able to synergize with a dose of radiation or chemical carcinogen that is insufficient to cause tumors by itself, such that a substantial number of animals will develop mammary tumors. Nutrition has an effect on mammary carcinogenesis because of its effect on the endocrine system. (58 refs)

- 79-2432 Potential Carcinogenic Effect of Sex Hormones During the Perinatal Period of Ontogenesis. (Rus) Ird, E. A. (Moscow, USSR); Smirnov, I. O. *Akush Ginekol (Mosk)* (12): 4-7; 1978.

Literature on the potential carcinogenic effect of transplacental exposure to various sex hormones is reviewed. Data on an increased risk of vaginal cancer in persons who had been exposed to synthetic estrogens in utero prompted the ban on the use of diethylstilbestrol during pregnancy. Experimental administration of estrogens to pregnant rats (0.04-1 mg, 2-4 doses) resulted in masculinization of the female progeny. Numerous cases of female hermaphroditism were reported in the offspring of women who, during 1950-1960, received synthetic progestins. Prolonged (up to 10 yr) use of androgenic progestins as oral contraceptives increases the incidence of benign and malignant tumors of the liver. (50 refs)

- 79-2433 Estrogens and Endometrial Carcinoma. (Ger) Zander, J. (I. Frauenklinik der Universitat, Maistrasse 11, D-8200 Munich 2, W. Germany) *Munch Med Wochenschr* 121(13): 443-444; 1979.

Two epidemiological studies from the US concerning the possible relationship between the use of estrogens in menopause and endometrial carcinoma are reviewed. A case-control study of 451 endometrial carcinoma patients and 888 controls demonstrated a sixfold risk of endometrial carcinoma among women using estrogens compared with controls. The risk was increased for both conjugated estrogens and diethylstilbestrol, and there was no distinct difference between cyclic and continuous treatment in terms of risk. The relative risk was 2.2 in women who had been treated with estrogens for <1 yr and 15 in women who had been treated for >5 yr. Another study demonstrated a risk factor of >10 for women who had been treated with estrogens for >5 yr and a recent decline in the incidence of endometrial carcinoma, possibly as a consequence of the less liberal use of estrogens. (2 refs)

- 79-2434 Carcinogenic Risks from Food—Real or Imaginary? Methodology in Assessing Carcinogenic Risk. (Eng) Grasso, P. (Occupational Health Unit, BP Res. Centre, Sunbury on Thames, Middx TW16 7LN, England) *Chem Ind* (February 3, 1979): 73-76; 1979.

The methodology involved in the administration of carcinogens to laboratory animals to assess carcinogenic risk is reviewed. The administration of carcinogens by the po route is emphasized because it is the most frequently used route in carcinogenicity testing and because it is thought to be the route most relevant to the assessment of carcinogenic risk from food. Rats and mice are the most commonly used test animals, followed by hamsters, dogs, and monkeys. Longevity and cost are major factors against use of the latter two species. With regard to the smaller rodents, choice of a hardy and preferably outbred strain with a known and stable background incidence of tumors is recommended. The use of two or three dose levels is recommended to reduce the effects of random variation, to demonstrate dose-response relationships, and to study tumor histogenesis. The use of max tolerated doses may invalidate the experimental results, in large part as a consequence of nonspecific injury to or irritation of the target tissue. Experiments should be terminated when the total incidence in the controls is approx 20%-25%. (10 refs)

- 79-2435 Naturally Occurring Carcinogens in Food. (Eng) Austwick, P. (Dept. Clinical Immunology, Cardiothoracic Inst., Univ. London, Fulham Road, London SW3, England); Mattocks, R. *Chem Ind* (February 3, 1979): 76-83; 1979.

Naturally occurring carcinogens in green plants and the production of carcinogens by fungi and actinomycetes are discussed. Plant carcinogens and other possible carcinogens that may reach human food include pyrrolizidine alkaloids, safrole, cycasin, bracken, nitrosamines, tannins, and sanguinarine. Among microorganisms, only the fungi and filamentous actinomycetes have been shown to produce carcinogenic toxins. The evidence for associations between actinomycetes and environmental carcinogens is small, but the potential role of these organisms in this problem requires more attention. In contrast to the actinomycete metabolites, most carcinogens from fungi have been detected in foodstuffs. These carcinogens include aflatoxins, sterigmatocystin, ochratoxin A, patulin, penicillic acid, luteoskyrin, cyclochlorotine, and 12',13'-epoxytrichothecenes. Only certain fungi produce the characteristic moldy flavor. Therefore, detection of fungal growth in food is a task for direct microscopy, mycology, and biochemistry, and the estimation of carcinogen content is a task for chromatography and bioassay. Where and when carcinogens are produced by fungi, and the amounts of carcinogens produced, are variable. It is likely that epidemiologic investigations will

show correlations between particular forms of cancer and mycotoxin occurrence. (63 refs)

- 79-2436 **Naturally Occurring Toxicants and Food Additives: Our Perception and Management of Risks.** (Eng) Hall, R. L. (Science and Technology, McCormick and Co., 11350 McCormick Road, Hunt Valley, MD 21031) *Nutr and Cancer* 1(2): 27-36; 1979.

The risks of food contaminants and additives are placed in perspective in a discussion of the various sources of food hazards, problems in interpreting dose-response data, and the wide variety of naturally occurring food toxins. The principal food hazards are those from microbiological and nutritional causes. Far more rare are hazards from environmental contaminants and natural food toxicants, followed by the extremely remote risks from pesticide residues and food additives. Probably the most debated issue in safety evaluation is whether, for any specific carcinogen or class of carcinogens, the dose-response curve is linear or curved. In the first case, every dose would produce some toxic response, and in the second case, an unfavorable response would not be produced until a threshold dose was reached. Steps that can be taken to reduce the hazards of naturally occurring food toxins include: exposure reduction, particularly by dietary choice; sanitation; and choice or limitation of geographic or taxonomic source. The chemical properties and means of controlling several natural food toxins are described. These include solanine, an intrinsic neurotoxin found in potatoes; islanditoxin, a hepatotoxic and carcinogenic metabolite of rice molds; cyanogenetic glycosides, which produce cyanide upon bruising in bamboo shoots, cherry seeds, cassava, and lima beans; carototoxin, a potent neurotoxin found in carrots and celery; aethusin, neurotoxin occurring in fool's parsley; coniine, a neurotoxin found in hemlock berries; saxitoxin, produced by dinoflagellates that may be consumed by edible shellfish; and the honey contaminants, tutin and hyenanchin. It is suggested that virtually every food contains natural toxicants and that if the present safety standards for food additives were applied consistently to all foods, we would have nothing left to eat. (no refs)

- 79-2437 **Public Health Problems Posed by the Use of Pesticides in Agriculture.** (Fre) Zamfir, G. (Institut d'Hygiene et de Sante Publique, Jassy, Rumania) *Sante Publique (Bucur)* 21(1/2): 63-70; 1978.

The long-term mutagenic, teratogenic, and carcinogenic effects of organochloride pesticides are discussed. This type of pesticide accumulates in the food chain (phyto- and zooplankton, fish, and birds), leading to ingestion of large amounts by man. (48 refs)

- 79-2438 **Nutritional Factors That May Be Involved in Cancer of the Bladder.** (Eng) Friedell, G. H. (St. Vincent Hosp., 25 Winthrop St., Worcester, MA 01604); Greenfield, R. E.; Cohen, S.M. *Nutr Cancer* 1(2): 82-88; 1979.

Studies of the relationship between nutrition and bladder cancer (BIC) are reviewed. Elevated amounts of kynurenine, hydroxykynurenine, acetylkynurenine, and kynurenic acid were excreted by 50% of a group of BIC patients who had no history of occupational exposure to aromatic amines. However, BIC patients with known exposure to industrial amines did not exhibit abnormal tryptophan (TP) metabolite excretion patterns. In another study, 17% of BIC patients from an urban area had abnormal TP metabolite excretion patterns, compared with 47% of a group of patients from an agricultural area. These results suggest that TP metabolites may have a role in the etiology of so-called spontaneous BIC, but probably have little to do with the development of industrial or environmental BIC. In Fischer rats fed the carcinogens N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT) or N-methyl-N-nitrosourea (MNU), both saccharin and sodium cyclamate acted as BIC promoters. In similar studies, TP also acted as a promoting agent. Pyridoxine (vitamin B6: 25 mg/day) restores an abnormal pattern of excretion of urinary TP metabolites to a normal pattern and also apparently diminishes the frequency of recurring BIC. Vitamin A and vitamin C also appear to have some beneficial effects in inhibiting the induction of BIC in experimental animals. (29 refs)

- 79-2439 **Diet and Old Age.** (Eng) Norden, A. (Dept. Medicine, Univ. Hosp., Lund, Sweden) *Scand J Gastroenterol Suppl* 14(52): 22-27; 1979.

Experimental, clinical, and epidemiological studies of the relationship between diet and old age are reviewed. Studies with rats indicate that conditions in early life govern the life-span and affect the development of age-related diseases, including cancer. Longevity correlates with the rate of wt gain during the early phase of life. Energy restriction during growth delays the development of a full immunological response in mice and prolongs the maintenance of immunological competence. Chronic energy restriction inhibits the formation of many types of tumors. Hepatic tumors, however, are stimulated by energy restriction. Epidemiological studies indicate that obesity is related to an increased tumor risk, particularly cancers of the intestinal tract, liver, gallbladder, breast, uterus, and genitourinary tract. A correlation has been reported in humans between fat consumption and breast cancer. It has been hypothesized that industrialization has affected cancer incidence by the mass refining of carbohydrates rather than by the addition of specific chemicals. The relation between trace elements and cancer has also been investigated. Iodine deficiency was related to

an increased incidence of thyroid cancer and magnesium deficiency was associated with thymoma, but copper appears to inhibit tumor induction. Conflicting findings have been reported for some of the other trace elements in relation to cancer. (40 refs)

- 79-2440 Dietary Fibre and Experimental Colon Cancer** (Letter to Editor). (Eng) Cruse, P. (Surgical Unit, Rayne Inst., Univ. Coll. Hosp. Medical Sch., London WC1E 6JJ, England); Lewin, M.; Clark, C. *Lancet* 1(8112): 376; 1979.

In response to criticisms of previous study of the possible modifying role of dietary fiber in dimethylhydrazine (DMH) carcinogenesis, it is stated that the dose of DMH was not excessive. In a parallel experiment in which rats received an identical DMH dose, 30% of those fed a fiber and cholesterol-free diet failed to develop colon carcinomas, and there was a highly significant prolongation of time to tumor presentation and of survival. A cholesterol-free diet was concluded to be a more powerful dietary modifier of DMN carcinogenesis than added dietary fiber (bran). It is agreed that human colon cancer is likely to have a multifactorial etiology. (8 refs)

- 79-2441 A Prudent Diet for the Nation.** (Eng) Mann, J. I. (Dept. Social and Community Medicine, Univ. Oxford and Radcliffe Infirmary, 8 Keble Road, Oxford OX1 3QN, England) *J Hum Nutr* 33(1): 57-63; 1979.

Nutritional factors in the etiology of coronary heart disease, maturity-onset diabetes, diverticular disease, and dental caries are discussed. The possibility that nutrition plays a role in the etiology of malignant large bowel tumors and other diseases is also noted. Recommendations for a prudent diet are outlined. Complex carbohydrates, especially whole grain cereals and unprocessed fruits and vegetables, should be increased at the expense of fats, simple sugars, and refined carbohydrates. In addition, as much as possible of the daily intake of fat should be in the polyunsaturated form. (24 refs)

- 79-2442 Discussion: Introductory Remarks.** (Eng) James, W. P. (Dunn Nutrition Unit, Old Addenbrookes Hosp., Trumpington St., Cambridge, CB2 1QE, England) *Nutr Cancer* 1(2): 89-103; 1979.

Papers presented at a symposium on nutrition and cancer are summarized following introductory remarks that emphasize the need for better techniques for assessing and validating the dietary habits and intake of individuals in cancer studies. The consensus seems to be that total caloric intake rather than a specific nutrient, such as fat, correlates

with a higher risk for breast cancer in women. In animal studies, however, fat can be considered as distinctive from total calories and the two sets of data seem to follow the same trend. Evidence presented in some papers points to an association between dietary fat and colon cancer or between animal protein, particularly beef consumption, and colon cancer. However, this issue is not clear because most of the dietary information is extremely crude and various studies have resulted in contradictory findings. The decline of gastric cancer seen in many parts of the Western world seems to be caused by the introduction of refrigeration and freezing rather than by the use of antioxidants. It is concluded that too little is known about the relationship between nutrition and cancer to make any recommendations about specific dietary changes to decrease cancer risk. There is a need for more scientific and sophisticated data collection and evaluation techniques regarding food intake and for more prospective studies. (5 refs)

- 79-2443 Mechanism of Action of Diet as a Carcinogen.** (Eng) Weisburger, J. H. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Dana Road, Valhalla, NY 10595) *Nutr Cancer* 1(2): 74-81; 1979.

The mechanism of the dietary induction of cancer of the stomach, breast, prostate, and colon is discussed. A typical population at high risk for gastric cancer consumes a diet high in carbohydrates with limited protein and limited micronutrients on an annual basis, and, of greater importance, low levels of select micronutrients, especially vitamin C, on a seasonal basis. Certain groups also have a predilection for pickled, highly salted, and smoked foods. A working hypothesis states that gastric cancer stems from the formation in the stomach or in pickled foods of alkylnitrosourea compounds. Vitamin C antagonizes the effect of nitrite with respect to the formation of carcinogenic nitrosamines. o-Methylarylamines, which cause colon and breast cancer in male and female rats, have been detected in broiled and fried protein-containing foods. It is possible that these compounds may be the actual carcinogens responsible for the colon and breast cancers. In one study, mutagens were detected in the stools of about half the healthy individuals screened. Whether these mutagens are derived from the metabolism of a mutagen in fried meats or whether they are derived from other precursors is not known. The amount of fecal mutagen can be reduced by increasing dietary fiber intake or by vitamin C. Selenium derivatives have been implicated as protective elements in cancer of the colon, and vitamin A and retinoids have been noted to reduce cancer development in the breast and bladder. (61 refs)

- 79-2444 Nutrition and Breast Cancer.** (Eng) Dickerson, J. W. (Div. Nutrition and Food Science, Dept. Biochemistry, Univ. Surrey, Guildford, Surrey, England) *J Hum Nutr* 33(1): 17-23; 1979.

Present evidence indicates that a high fat intake may be one factor in the etiology of breast cancer (BC). Overnutrition and early menarche, which is influenced by nutritional status, are associated with a high incidence of BC. In experimental animals and humans, there appears to be a correlation between body wt and tumor development, and animals on high-fat diets are more susceptible to the induction of BC by chemical carcinogens. Mortality from BC in humans is strongly positively correlated with animal protein and fat intake. A chronic high fat intake elevates serum prolactin levels and thus raises the prolactin:estrogen ratio, promoting tumor cell growth. The plasma of postmenopausal women with BC contains higher concentrations of total lipids, phospholipids, cholesterol, and lipase activity than that of age-matched women with cancers of other sites. Thiamine deficiency, low WBC ascorbic acid concentrations, hypercalcemia, hypercalciuria, and disturbed tryptophan metabolism have also been reported in BC patients. It is possible that the progress of the disease is associated with an increasing requirement for thiamine and that large amounts of ascorbic acid could be of therapeutic value for BC patients. (41 refs)

- 79-2445 **Preneoplasia in Breast Cancer.** (Eng) Medina, D. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX 77030) In: *Breast Cancer 2: Advances in Research and Treatment*. McGuire, W. L., ed. (New York: Plenum Medical Book Company): 407 pp.; 47-102; 1978.

Studies of preneoplastic (PNP) mammary lesions are reviewed with emphasis on the cellular and cell-population characteristics of precursor mammary populations. The principal PNP lesion in mouse mammary glands is the hyperplastic alveolar nodule (HAN), which can be induced by viruses, chemical carcinogens, and prolonged hormone stimulation. In addition to HAN's, two other types of lesions have been identified, ductal hyperplasias and foci of keratinizing alveoli (keratinized nodules: KN). The in vivo behavioral properties of PNP lesions are often intermediate between those of normal and neoplastic tissues; some properties are completely opposite those of neoplastic populations. Their response to hormonal agents and cytostatic drugs suggests that a qualitative change occurs in the transformed cells as they progress from a PNP to a neoplastic state. There appears to be no simple correlation between carcinogen-induced immunosuppression and tumorigenesis in mammary tumors arising in PNP outgrowths. Limited scanning electron microscopy information on normal, PNP, and neoplastic mammary cells in vitro suggests that there are no major differences in surface attachment patterns, microvilli, or number and degree of surface distortions. Neither alterations in cytoplasmic microtubules and microfilaments nor lectin agglutination appear to be of value in distinguishing between normal and PNP mammary cells. It is not clear whether nuclear

magnetic resonance techniques are able to distinguish between normal and PNP states in the breast. (173 refs)

- 79-2446 **Gene Expression in Normal and Neoplastic Breast Tissue.** (Eng) Rosen, J. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX 77030) In: *Breast Cancer 2: Advances in Research and Treatment*. McGuire, W. L., ed. (New York: Plenum Medical Book Company): 407 pp.; 337-393; 1978.

This review covers the isolation and characterization of individual rat and mouse milk protein messenger RNA's (mRNA's) and mouse mammary tumor virus (MMTV) RNA, the synthesis of their respective complementary DNA's (cDNA's), and their use in studies of the hormone regulation of gene expression. Casein mRNA was demonstrated in 70% of >30 7,12-dimethylbenz(a)anthracene (DMBA)-induced tumors assayed by molecular hybridization. However, casein mRNA levels were usually $\leq 10\%$ of those observed in an 8-day lactating mammary gland. Casein mRNA was not detected by molecular hybridization using a mouse 15S casein mRNA-cDNA probe in a number of hormone-independent mouse mammary tumor lines. Very low levels of casein mRNA were detected in D2 hyperplastic alveolar nodule tissue, and no detectable sequences were found in autonomous D2 mouse tumors. Therefore, the expression of the casein gene appears to be repressed during mouse mammary tumorigenesis. Very low levels of MMTV RNA were detected in normal mammary tissues. However, high levels of endogenous virus expression were found in the D2 nodules, and a significant number of MMTV RNA sequences were present in the transplantable D2 tumors. Radioimmunoassay of casein in the serum of normal and breast cancer patients indicated the presence of casein in patients with both primary and metastatic breast cancer, but not in normal nonpregnant women. However, negative results for breast cancer patients were obtained in a different laboratory. Thus, the usefulness of casein determination as a diagnostic assay for human breast cancer is unresolved. (149 refs)

- 79-2447 **Non-Trophoblastic Tumours of the Placenta.** (Eng) Fox, H. (Dept. Pathology, Univ. Manchester, Manchester, England) *Major Probl Pathol* 7: 343-367; 1978.

The incidence, origin, pathology, and clinical features of primary and secondary nontrophoblastic tumors of the placenta are reviewed. The only primary types known to occur are hemangiomas and teratomas. Hemangiomas, which probably arise as malformations of the primitive angioblastic tissue of the early placenta, are found in approx 1% of placentas. Hemangiomas are mainly considered to be hamartomatous malformations rather than

true neoplasms. Most are of no clinical importance, but they may cause complications affecting the mother, fetus, or neonate. Teratomas are benign tumors arising from germ cells. They are quite rare and are distinguished from a fetus acardius amorphus by their lack of an umbilical cord and lack of axial organization. Placental neoplasms may also occur as metastases from maternal or fetal neoplasms. Maternal metastases to the placenta occur only in women with widely disseminated malignant disease, and they are most common in patients with malignant melanomas or carcinomas of the breast or bronchus. In the case of malignant melanoma, malignant cells may pass over to the fetus. The dissemination of fetal malignant disease to involve the placenta is extremely uncommon. Neuroblastoma is the only solid fetal tumor reported to have spread to the placenta. There are also examples of fetal leukemia with placental villous involvement. (132 refs)

- 79-2448 **Leukemia in Small Ruminants.** (Rus) Kunakov, A. A. (No affiliation given) *Veterinariia* (12): 76-78; 1978.

Current data on the incidence of leukemia in sheep and goats are reviewed. Clinical manifestations of the disease include wt loss and loss of appetite, paresis of the hind extremities, and tumor formations in the extremities or along the vertebral column. The duration of survival is 2-3 wk. The incidence of leukemia has been found to range from 12/24,080 to 46/1,000,000. (no refs)

- 79-2449 **Infectious and Chronic Disease Epidemiology: Separate and Unequal?** (Eng) Barrett-Connor, E. (Div. Epidemiology, Dept. Community Medicine M-007, Sch. Medicine, Univ. California at San Diego, La Jolla, CA 92093) *Am J Epidemiol* 109(3): 245-249; 1979.

The division of epidemiology into the subspecialties of infectious disease and chronic disease is discussed. Epidemiologically, acute diseases differ from chronic diseases in two major aspects: immediacy of response and uniqueness of observation. Acute and chronic disease epidemiologists have important lessons to offer each other, and the division between epidemiology and epidemiologists into the two subspecialties is detrimental to the study of disease. (13 refs)

- 79-2450 **Pancreas Cancer (Non-endocrine): A Review--Part II.** (Eng) Cubilla, A. L. (Dept. Pathology, Sloan-Kettering Memorial Cancer Center, New York, NY); Fitzgerald, P. J. *Clin Bull* 8(4): 143-155; 1978.

Findings from a retrospective and a prospective study of nonendocrine pancreatic cancer (PC) are reviewed. The increased risk of PC in diabetics is greater than that for any other cancer, especially in women. In the retrospective

study, smoking significantly increased the risk in men. In neither study was there evidence that alcohol increased the risk, but tobacco and alcohol may be cocarcinogens in a small number of patients. There was no consistent combination of factors that might identify asymptomatic patients with early PC. Approx two-thirds of the patients in both studies had Stage III disease at diagnosis. The presence of marked atypia and carcinoma in situ in the duct epithelium adjacent to the cancers suggests that the duct cell is the origin of mucin-producing adenocarcinomas. The high incidence of perineural invasion probably contributes to the retroperitoneal spread and very poor prognosis. The incidence of carcinoma in situ in the duct epithelium of resected specimens suggests that there may be a sufficiently long in situ cancer phase, during which new techniques could be used to detect the disease. These techniques may include detection of pancreatic oncofetal antigen, determination of serum pancreatic ribonuclease levels, the leukocyte adherence inhibition assay, and ultrasonography. (85 refs)

- 79-2451 **Role of Genetic Factors in the Etiology of Esophageal Cancer.** (Eng) Kasenov, K. U. (Dept. Pathophysiology, Medical Inst., Aktiubinsk, USSR) *Vopr Onkol* 25(2): 68-72; 1979.

Data pertaining to the potential role of genetic factors in the etiology and pathogenesis of esophageal cancer are reviewed. Significant differences in the incidence of this cancer among ethnic groups might be indicative of a genetic predisposition. The incidence of esophageal cancer was almost two times higher among relatives of the patients than in a control sample. However, it is strongly emphasized that the results of population and pedigree analyses can also be interpreted as being indicative of similar environmental factors. (37 refs)

- 79-2452 **The Costenbader Memorial Lecture. Genesis and Genetics of Retinoblastoma.** (Eng) Francois, J. (De Pintelaan 135, B-9000 Ghent, Belgium); DeBie, S.; Matton-Van Leuven, M. T. *J Pediatr Ophthalmol Strab* 16(2): 85-100; 1979.

Studies of the development and genetics of retinoblastoma (RB) are reviewed. The incidence of RB is 1/20,000 live births, and 16%-19% of affected children die. About 94% of all RB cases are sporadic and 6% are familial. Hereditary RB's, whether sporadic or familial, represent 40% of all cases. The delayed mutation and multistage mutation hypotheses can explain the clinical characteristics of sporadic and familial RB. The multistage mutation theory, which postulates that at least two mutational events are necessary to convert a normal retinal cell into a RB cell, best fits the observed behavior of RB's. This model, however, does not exclude delayed mutation in the process

leading to the first mutation. RB patients and affected families have a relatively high susceptibility to the development of other malignant tumors, particularly osteogenic sarcomas. The pathological gene for RB may be acquired by a somatic mutation, a germinal mutation, or a chromosome aberration. A new dominant germinal mutation is responsible for 100% of the bilateral sporadic cases and for 10%-15% of the unilateral sporadic cases. A deletion of the long arm of a chromosome (13q14) may be the cause of some, if not all, RB's. (125 refs)

- 79-2453 The Surface Properties of Invasive and Metastatic Tumour-Cell Populations (Meeting Abstract).** (Eng) Poste, G. (Dept. Experimental Pathology, Roswell Park Memorial Inst., Buffalo, NY 14263) *Br J Cancer* 39(4): 467-469; 1979 (19 refs)

- 79-2454 Morphology and Histogenesis of Precancerous Lesions of Cervix Uteri.** (Rus) Iakovleva, I. A. (Dept. Pathomorphology, Moldavian Res. Inst. Oncology, Kishinev, USSR) *Akush Ginekol (Mosk)* (12): 12-15; 1978.

The histological features of various precancerous lesions in the cervix uteri are reviewed. The most frequent precancerous lesion is dysplasia; dysplasia is transformed into carcinoma in situ in 40%-64% of the cases. In 89% of the cases, the dysplasia developed from endocervicitis (pseudoerosion) or during epidermization. In young women, dysplasias are usually diagnosed in the squamous epithelium of the vaginal region of the cervix, but in women >40 yr old, dysplasias are located in the cervical canal. Precancerous changes in the cervix also include leukoplakia, erythroplakia, metaplasia, and adenomatosis. (14 refs)

- 79-2455 The Aetiology of Thyroid Tumours.** (Eng) Williams, E. D. (Welsh Natl. Sch. Medicine, Glamorganshire, Wales) *Clin Endocrinol Metab* 8(1): 193-207; 1979.

The etiology of the major types of human thyroid cancer (papillary, follicular, anaplastic, and medullary carcinoma, and lymphoma) is reviewed. Papillary carcinoma, the most common type of thyroid cancer, is derived from thyroid follicular cells. Thyroid-stimulating hormone (TSH) plays a permissive but not initiating role. The tumor is more common in areas with an iodide-rich diet and more common in some races than others. It can be induced by radiation, at very low doses. Follicular carcinoma occurs more commonly in iodide-deficient areas and is regarded as a TSH-induced tumor. It may also be induced by radiation. Anaplastic carcinoma of the spindle or giant cell type arises from a preexisting differentiated carcinoma. Radiation

and, possibly, viruses are implicated in this transformation. This tumor has an extremely rapid growth rate compared with papillary and follicular carcinomas. There are no known racial or genetic factors involved in the etiology of anaplastic carcinoma. Medullary carcinoma is the only thyroid tumor with a genetic etiology. In the 80% of tumors that are sporadic, the roles of dietary calcium, dietary vitamin D, and radiation remain speculative. Malignant lymphoma is a disease of the elderly, with a marked female preponderance. The great majority of primary lymphomas of the thyroid arise in glands showing severe thyroiditis. (59 refs)

- 79-2456 The Approach to the Irradiated Thyroid.** (Eng) Witt, T. R. (Dept. General Surgery, Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612); Meng, R. L.; Economou, S. G.; Southwick, H. W. *Surg Clin North Am* 59(1): 45-63; 1979.

The occurrence and management of pathology resulting from irradiation of the thyroid are reviewed. The mechanism of radiation-induced thyroid carcinogenesis probably involves both injury to the thyroid and effects on the hypothalamic-pituitary axis that lead to elevated thyroid-stimulating hormone levels. The risk of thyroid cancer appears to increase linearly with radiation doses between 20 and 1,125 rads. The incidence of both thyroid cancer and benign thyroid disease are increased by irradiation of the thyroid. The malignancies tend to be well-differentiated, with papillary, follicular, and mixed papillary-follicular types predominating. The clinical recurrence rate in irradiated patients is also increased. Detection of irradiation-associated thyroid disease has been greatly improved by mass screening and patient recall programs. Physical examination, thyroid scan, and examination of biopsied tissue are the most reliable indicators of thyroid malignancies. (69 refs)

- 79-2457 Reemergence of Thyroidectomy as Treatment for Graves' Disease.** (Eng) Klementschtch, P. (Dept. Surgery, Univ. Chicago Hosp., Box 402, 950 E. 59th St., Chicago, IL 60637); Shen, K.; Kaplan, E. L. *Surg Clin North Am* 59(1): 35-44; 1979.

Because of the potential long-term risks of radioiodine therapy, the popularity of thyroidectomy as the definitive treatment for Graves' disease is growing. These potential risks include progressive hypothyroidism, leukemia, genetic abnormalities, and thyroid carcinoma. (26 refs)

- 79-2458 Well-differentiated Carcinomas of the Thyroid.** (Eng) Block, M. A. (Dept. Surgery, Henry Ford Hosp., Detroit, MI) *Curr Probl Cancer* 3(8): 1-60; 1979.

The essential features of well-differentiated thyroid carcinomas (WDTC) are presented. WDTC include the papillary (Pap) and follicular (Fol) varieties and their subsets. In the US, the Pap variety is the most common type of TC. In areas of Europe with high rates of endemic goiter, Fol carcinomas predominate, although the incidence of Pap carcinoma is increasing. The histologic features of WDTC approximate those of normal tissue to varying degrees. Except for the high-grade angioinvasive Fol carcinomas and the Pap or Fol carcinomas with anaplastic elements, WDTC are generally indolent and very slow-growing. WDTC remain occult with a significant frequency and never have an impact on the health of numerous individuals. They present commonly as a nodule in the neck, usually in the thyroid, but occasionally in a cervical lymph node. The presence of microscopic foci of calcification, psammoma bodies, is a specific identifying factor for Pap carcinoma. Little dedifferentiation may be present. There is a predisposition for dissemination via the lymphatic system and for a multifocal origin. Fol carcinoma is composed microscopically of follicles of relatively uniform size but smaller than normal. It is divided into the low-grade, well-encapsulated and the high-grade, angioinvasive varieties. The incidence of multicentricity and bilateral occurrence is increased in WDTC associated with external radiation therapy. A history of previous external radiation to the head and neck; a recently detected, firm, single nodule in the thyroid, especially in a man; ipsilateral cervical lymphadenopathy; a recent appearance of a single thyroid nodule in a patient >40 yr old; or rapid growth of a firm nodule point to a high degree of likelihood of carcinoma for a few thyroid nodules. A variety of tests to facilitate the identification of nodules likely to represent carcinoma are described. (36 refs)

- 79-2459 Clinical Features of Thyroid Tumours.** (Eng) Taylor, S. (Royal Postgraduate Medical Sch., London, England) *Clin Endocrinol Metab* 8(1): 209-221; 1979.

Clinical features of thyroid tumors in 355 patients treated from 1950 to 1975 are discussed. All thyroid tumors, with the exception of medullary carcinoma, are at least twice as common in women as in men. Papillary tumors present as a hard mass in the gland and involved lymph nodes are usually mobile but firm. X-rays may reveal fine stippling due to calcification. Radioisotope scanning will show cold areas where the gland is replaced by tumor. Hoarseness due to paralysis of the vocal cord makes malignancy almost certain. Follicular carcinoma occurs as a solitary, well-encapsulated nodule in the thyroid; it is typical of areas where goiter is endemic. Follicular nodules are usually fairly hard on palpation, occasionally show calcification, and are almost invariably cold on scanning. Anaplastic carcinoma affects old people, mostly women >65. The mass is often multinodular and fixed to surrounding tissues. Anaplastic thyroid tumors spread by direct extension into

the tissues and also by lymphatics and the blood stream. Medullary thyroid carcinoma is a tumor of the calcitonin-secreting parafollicular C-cells. Initial spread is typically by the lymphatics; later, it spreads to the liver and skeleton. Diagnosis rests on the detection of raised plasma calcitonin levels either basally or after stimulation. Lymphoma of the thyroid is associated with autoimmune thyroiditis. Histologically, it consists of small round cells and central, deeply staining nuclei. Rare tumors of the thyroid include teratoma, sarcoma, and squamous cell carcinomas. (23 refs)

- 79-2460 Thyroid Nodules.** (Eng) Beckers, C. (Univ. Louvain, Medical Sch., Brussels, Belgium) *Clin Endocrinol Metab* 8(1): 181-192; 1979.

The clinical status of patients with thyroid nodules, the laboratory evaluation of the nodules and, the pathophysiology of thyroid nodule formation, are reviewed. When nodules are present, the functional status and the morphology of the thyroid gland must be evaluated. The nodular transformation of thyroid tissue results from the interplay of several mechanisms, the most important of which is probably alternate periods of iodine deficiency and iodine repletion. (60 refs)

- 79-2461 Pathology of the Membranes.** (Eng) Fox, H. (Dept. Pathology, Univ. Manchester, Manchester, England) *Major Probl Pathol* 7: 458-472; 1978.

Pathology of extraplacental membranes is reviewed. Abnormalities of the amniotic epithelium include pseudostratification, epithelial disorganization, epithelial cell necrosis, "basket" deformities, and giant goblet cells. Squamous metaplasia is seen on the surface of the amnion and umbilical cord in foci consisting of layers of stratified squamous epithelial cells. It is of no clinical or pathological significance. Amnion nodosum, in which the fetal surface of the amnion is studied with multiple small nodules consisting of deposits of vernix caseosa, should serve as a warning of the possibility of a congenital abnormality in the neonate. Amniotic polypi are derived from the amniotic epithelium; their significance is unknown. Premature rupture of the membranes during the later months of pregnancy, extramembranous pregnancy, extraamniotic pregnancy, and amniotic band formation, a complication of early amniotic rupture, are also covered topically. (77 refs)

- 79-2462 Endocrine Secretions by Lung Carcinomas.** (Fre) Huchon, G. (Centre de Pneumologie, Hopital Tenon, 4, rue de la Chine, 75970 Paris Cedex 20, France); Akoun, G. *Sem Hop Paris* 55(3/4): 180-188; 1979.

Studies of ectopic hormone secretion by lung carcinomas

are reviewed. The overall frequency of endocrine hormone-secreting lung carcinomas is estimated at 10%. Parathyroid hormone is secreted by epidermoid carcinomas, calcitonin by small cell anaplastic carcinomas and carcinoid adenomas, antidiuretic hormone by small cell anaplastic carcinomas, ACTH and melanocyte-stimulating hormone by small cell anaplastic carcinomas and carcinoid adenomas, and gonadotropins (human chorionic gonadotropin, luteinizing hormone, and follicle-stimulating hormone) by all histologic types of lung carcinoma. Hypotheses concerning these ectopic secretions are given. (92 refs)

- 79-2463 Cell Surface Glycoproteins and Malignant Transformation.** (Eng) Yamada, K. M. (Lab. Molecular Biology, NCI, Bethesda, MD 20014); Pouyssegur, J. *Biochimie* 60(11/12): 1221-1223; 1978.

The role of cell-surface glycoproteins in cell adhesion, cell-cell recognition, uptake of nutrients, and growth control during malignant transformation is reviewed. Alterations in cell behavior that occur after malignant transformation are summarized briefly, and the many accompanying changes in individual cell-surface proteins are described in detail. Two major approaches have provided insight into the causal relationships of glycoprotein changes to altered properties of transformed cells: (1) isolation, characterization, and reconstitution of each cell-surface component, and examination of the ability of the reconstituted protein to restore functions altered in transformed cells; and (2) isolation and characterization of cell mutants in each specific function, and examination of which aspects of transformation result from alterations in each function. The apparent relationships between altered cell-surface proteins and biological properties found in many transformed cells are outlined schematically. In the fibroblast tissue culture model, many characteristics of transformed cells, such as morphology and cell alignment, appear to depend on cell adhesion, which is often defective due to alterations in fibronectin, cyclic AMP, and cell-surface carbohydrates. Many of these defects can be reproduced by altering adhesion, whether by inhibiting glycosylation, inactivating fibronectin, or by growing cells on poorly adhesive substrates. (188 refs)

- 79-2464 Trophoblastic Tumours of the Placenta.** (Eng) Fox, H. (Dept. Pathology, Univ. Manchester, Manchester, England) *Major Probl Pathol* 7: 368-425; 1978.

The pathology of trophoblastic disease is reviewed, with particular emphasis on the clinico-pathological aspects of hydatidiform mole and gestational choriocarcinoma. Histologically, the following types of 'choriomas' were recognized originally; hydatid mole, chorioadenoma

destruens, choriocarcinoma, syncytial endometritis, and syncytioma. The precise cause of gestational trophoblastic tumors remains obscure, but the tumors show a marked geographical variation in distribution, and genetic factors appear to play a part in their etiology. A hydatidiform mole may be regarded as an abnormal product of gestation, and it is considered to be invasive when molar villi have penetrated into the myometrium or its blood vessels. Its histopathology, ultrastructure, pathogenesis, and prognosis are reviewed. Choriocarcinoma is composed of both cytotrophoblasts and syncytiotrophoblasts, but it is without chorionic villi. The most striking clinical feature of this tumor is the remarkable reversal in mortality brought about by the introduction of cytotoxic therapy. Its histopathology, macroscopic and microscopic appearance, metastatic spread, diagnosis and immunological aspects are surveyed. (174 refs)

- 79-2465 Asbestos and Mesothelioma.** (Ger) Ferlinz, R. (Abteilung für Pneumologie, Klinikum der Universität Mainz, Langenbeckstrasse 1, 6500 Mainz, W. Germany); Endres, P. *Dtsch Med Wochenschr* 103(6): 1055-1056; 1978.

The relationships between asbestos exposure and lung cancer and pleural and peritoneal mesothelioma are reviewed. A dose-effect relationship is probable in the case of mesothelioma. Recent studies suggest an increased incidence of malignant gastrointestinal tumors in patients with asbestosis. (3 refs)

- 79-2466 Talc in Normal and Malignant Ovarian Tissue (Letter to Editor).** (Eng) Henderson, W. J. (Tenovus Inst. Cancer Res., Welsh Natl. Sch. Medicine, Cardiff CF44XX, Wales); Hamilton, T. C.; Griffiths, K. *Lancet* 1(8114): 499; 1979.

Confirmatory evidence from a 1971 report showing that talc particles were present in certain ovarian and uterine cervix tumor tissue and normal tissue is cited to refute an editorial statement that the original report was probably erroneous. (13 refs)

- 79-2467 Risks and Benefits of the Treatment of Psoriasis.** (Eng) Epstein, J. H. (Univ. California Sch. Medicine, San Francisco, CA 94108) *N Engl J Med* 300(15): 852-853; 1979.

Problems related to the treatment of psoriasis are reviewed briefly. Treatment with coal tar and short-range UV radiation has not resulted in noteworthy skin cancer formation, despite their usage for >50 yr. In contrast, the use of combined psoralens and long-range UV radiation has been

associated with an epidermal cancer incidence 2.63 times that expected for a control population. This may be due to the fact that most patients require maintenance psoralen photochemotherapy at relatively short intervals. This type of therapy must still be considered experimental. (13 refs)

- 79-2468 Immunologic Surveillance Revisited.** (Eng) Moller, G. (Dept. Immunobiology, Karolinska Int., Wallenberglab., Lilla Frescati, S-104 05, Stockholm 50, Sweden); Moller, E. *Transplant Proc* 11(1): 1041-1046; 1979.

Evidence for the monoclonality of tumors is discussed, and the relationship between genetic changes, immunodeficiency, and cancer is considered. A variety of lymphatic tumors are of monoclonal origin, including Waldenstrom's macroglobulinemia, chronic lymphatic leukemia, and chronic lymphosarcomatous leukemia. Other tumors from a variety of anatomical locations, including carcinomas, sarcomas, and various lymphoid tumors are also monoclonal. It is suggested that carcinogens may only accelerate the appearance of rare genetic changes leading to neoplasia. The concept that carcinogens cause tumors by a genetic mechanism is supported by the evidence that mutagenicity and carcinogenicity occur in parallel, provided the carcinogens have been metabolized in the body. If the concept of immune surveillance were true, tumors in immunosuppressed individuals would not be monoclonal. It appears, however, that such tumors are monoclonal. It is concluded that a major mechanism of carcinogenesis by chemical and physical carcinogens is somatic mutations caused by errors during the repair of DNA damaged by carcinogens. (23 refs)

- 79-2469 Acute Leukemia and Immunosuppressive Drug Use. A Review of Patients Undergoing Immunosuppressive Therapy for Non-neoplastic Diseases.** (Eng) Grunwald, H. W. (Div. Hematology, Queens Hosp. Center Affiliation, Long Island Jewish-Hillside Medical Center, 82-68 164th St., Jamaica, NY 11432); Rosner, F. *Arch Intern Med* 139(4): 461-466; 1979.

Sixty-one reported cases of acute leukemia developing in patients who had previously received immunosuppressive agents for nonneoplastic disorders are reviewed. In three patients, the diagnosis of acute leukemia was made <6 mo after the first exposure to immunosuppressive drugs and was, therefore, considered coincidental. Among the remaining 58 patients, most diagnoses were of myeloblastic or myelomonocytic leukemia. The interval from immunosuppressive therapy to the development of acute leukemia ranged from 0.75-18 yr, with a mean of 4.8 yr. The underlying diagnoses in most of the 58 patients were rheumatoid arthritis or renal disease, or the patients were renal transplant recipients. Thirty patients had received

alkylating agents exclusively, 10 had received antimetabolites only, and the remaining 18 patients had received multiple therapeutic modalities including antimetabolites, alkylating agents, and/or radiation. Most patients had also received large amounts of corticosteroids. Although the overall denominator of population at risk is not known, the relatively high proportion of patients who had received alkylating agents before developing acute leukemia does suggest a causal relationship. (71 refs)

- 79-2470 Surface Antigens on Human Herpesvirus-infected and -transformed Cells.** (Eng) Lausch, R. N. (Dept. Microbiology, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA 17033); Rapp, F. In: *Virus Transformed Cell Membranes* 373-396; 1978.

The expression of virus-associated antigens on the surface of cells infected or transformed by the human herpesviruses, herpes simplex virus (HSV), cytomegalovirus (CMV), and Epstein-Barr virus (EBV), is reviewed. Virus-associated antigens can be demonstrated on the surface of cells transformed by HSV, CMV, and EBV by a variety of serological assays. Antigens are also demonstrable in cellular immunity tests. Serum from virus-immunized hosts can specifically block the cytotoxicity of sensitized lymphocytes for HSV- or CMV-transformed cells, indicating that the humoral and cellular immune responses are probably directed against similar antigenic determinants. There is evidence that the membrane antigens (MA) found on transformed cells are also expressed on infected cells and on the virion envelope, which indicates that the antigens are coded for by the virus genome. There is no evidence of cross-reacting virus-associated membrane antigens on cells transformed by HSV, CMV, or EBV. The occasional spontaneous regressions observed in Burkitt's lymphoma patients may be the result of a cellular immune response to EBV surface markers. Immunization of syngeneic hosts with HSV or CMV has not resulted in protection against challenge with homologous tumor cells. Thus, MA may not function as a transplantation rejection antigen; alternatively, antibody may interfere with cell-mediated immunity via masking of antigen or induction of antigen modulation. (149 refs)

- 79-2471 Viruses and Mammary Carcinoma.** (Eng) Schlom, J. (NCI, NIH, Bethesda, MD 20014); Colcher, D.; Drohan, W.; Kufe, D.; Teramoto, Y. A. In: *Breast Cancer 2: Advances in Research and Treatment*. McGuire, W. L., ed. (New York: Plenum Medical Book Company): 407 pp.; 23-46; 1978.

Cell culture, nucleic acid, and immunological studies of murine mammary tumor viruses (MMTV's) are reviewed. Growth of mouse mammary tumors in densely seeded

primary mammary tumor cultures containing insulin and hydrocortisone allows the production of pure MMTV from all mouse strains examined. Molecular hybridization studies indicate that the viral genomes of the 60S-70S RNA's of MMTV's released from early mammary tumors of several mouse strains are at least 95% related in their nucleic acid sequences. There is a substantial difference, however, between the MMTV released from early C3H mammary tumors and that released from late C3H mammary tumors. Molecular hybridization and recycling experiments demonstrate that there are proviral sequences in early mammary tumors that are non-germ line-transmitted. The only mouse strain examined in which these recycled MMTV(C3H) sequences are found in apparently normal livers is the GR mouse, a strain in which there is genetic evidence for a one-gene dominant characteristic for MMTV. Qualitative differences between MMTV's of different mouse strains were also determined by the thermal analysis of hybrids. MMTV's derived from different mouse strains contain both type-specific and group-specific reactivity, both of which are associated with the 52,000-dalton major external glycoprotein (gp52) of the MMTV virion. The type and group specificities of MMTV's grown in feline cells are indistinguishable from those observed in murine-grown MMTV's, providing strong evidence that the MMTV gp52 antigens are virus-coded. (37 refs)

- 79-2472 Genetic Regulation of Expression of Endogenous Viruses in Mice.** (Pol) Dus, D. (Zaklad Immunologii Nowotworow, Instytut Immunologii i Terapii, Doswiadczalnej PAN, Czerska 12, 53-114 Wroclaw, Poland); Szkudlarek, J.; Radzikowski, Cz. *Postepy Hig Med Dosw* 32(6): 683-702; 1978.

Studies of the genetic regulation of endogenous oncornavirus expression in mice and on the transmission, activation, and biological role of these viruses are reviewed. C-type endogenous viruses in mice can be activated by halogenated derivatives of pyrimidine, protein synthesis inhibitors, amino acid analogs, herpesvirus, and by the graft-vs-host reaction. The endogenous virus MTV-X, which induces mammary cancer in mice, is activated in vivo by ionizing radiation. (93 refs)

- 79-2473 Virus-associated Cell Surface Products: Relevance to Malignant Transformation** (Meeting Abstract). (Eng) Wyke, J. (ICRF, London, England). *BR J Cancer* 39(4): 458-459; 1979. (no refs)

- 79-2474 RNA Tumor Virus Genes and the Transforming Genes: Genetic Transmission, Infectious Spread, and Modes of Expression.** (Eng) Todaro, G. J.

(Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD 20014) *Natl Cancer Inst Monogr* (48): 199-213; 1978.

The genetic conservation and evolution of virogenes in mammalian species are described in relation to the horizontal, vertical, and congenital transmission of C-type RNA oncogenic viruses within members of a given species or among members of near and/or distantly related species. Examples of oncogenic virus infection between ancestors of the mouse, cat, pig, and primates as well as integration of the virus into the host's genome are documented. There are several possible normal functions of the virogenes as a part of the cellular genome of many species. They may play a role during development, they may provide protection against diseases caused by related but more virulent viruses, and they may provide protection on an immunological basis against cancer. Recent evidence of genetic recombination (genetic mixing) among distinct C-type viruses is also reviewed, thus completing an overview of the evolutionary past, present, and complex future relationships of oncogenic RNA viruses and mammalian species. - 79-2475 Glycolipids in Virus-transformed Cells.** (Eng) Steiner, S. (Dept. Virology and Epidemiology, Baylor Coll. Medicine, Houston, TX 77030); Steiner, M. R. In: *Virus-transformed Cell Membranes*. Nicolau, C., ed. (London: Academic Press): 393 pp.; 91-110; 1978.

Studies of glycolipid composition and metabolism in tumor cells are reviewed. Alterations in glycolipid metabolism have been found in human solid tumors and in leukemic lymphocytes. Cells transformed by DNA and RNA tumor viruses show a decrease in the more complex glycolipids. The specific glycolipid alteration is a function of both the particular cell line and the transforming virus. Glycolipid metabolism varies not only as a function of oncogenic transformation but also, in untransformed cells, as a function of cell population density. Gangliosides may serve as receptors for molecules such as interferon and the plant lectin ricin. The possible function of gangliosides as surface membrane receptors implies that the lipids are located on the surface membrane and are external and accessible. An alteration in glycolipid antigenicity, which may be related to a change in accessibility, has been observed in virus-transformed cells. There are also immunological differences between normal and transformed cells that appear to be related directly to differences in their glycolipid composition. The composition and distribution of amino acyl fucosides, neoproteolipids, and phospholipids also differs between normal cells and their transformed counterparts. The particular changes may be a function of both the transforming agent and the specific affected cell, which would account for the pleiotropic alterations encountered in neoplastic cells. (114 refs)

- 79-2476 Surface Proteins of Virus-transformed Cells.** (Eng) Vaheri, A. (Dept. Virology, Univ.

Helsinki, Helsinki, Finland) In: *Virus Transformed Cell Membranes*. Nicolau, C., ed. (New York: Academic Press): 408 pp.; 1-89; 1978.

The mechanism and significance of surface protein changes that occur during viral transformation are reviewed. For most in vitro work on viral oncogenesis and transformed cells, diploid fibroblasts or untransformed established fibroblastic cell lines are used to represent normal cells. Hematopoietic cells and human glial cells are also used. Fractionation, specific labeling of cell-surface proteins, polyacrylamide gel electrophoresis, and immunochemical

methods are among the techniques used to study cell-surface proteins. Particular emphasis is placed on the interactions, during transformation, between surface proteins and other cell-surface components, ie, membrane proteins, lipids, submembranous structures, and external glycosaminoglycans, and extracellular components such as plasma proteins, enzymes, and their inhibitors. The functional aspects of altered surface proteins in normal cell physiology and in the mechanism of viral transformation are stressed. Although working hypotheses and the prospects arising from the data are discussed, there is no attempt to construct unifying theories. (618 refs)

CHEMICAL CARCINOGENESIS

79-2477 Study of Phospholipid Absorption by Chrysotile Fibers: Comparison of Chemical and Photoelectron Spectrometric (XPS Method) Data. (Fre) Jaurand, M. C. (Laboratoire de Biopathologie pulmonaire, C.H.U. Henri-Mondor 51, avenue du Marechal-de-Lattre-de-Tassigny, 94000 Creteil, France); Thomassin, J. H.; Magne, L.; Baillif, P. *C R Acad Sci [D] (Paris)* 288(2): 279-282; 1979.

The adsorption of synthetic dipalmitoyl phosphatidylcholine (DPPC) by chrysotile fibers was studied following a 15-min incubation at 37 C. The max adsorption was approx 130 µg/mg chrysotile. The results are in good agreement with the bilayer adsorption hypothesis. (13 refs)

79-2478 Thymectomy and Asbestos-induced Mesotheliomas in Rats. (Eng) Wagner, M. M. (Pneumoconiosis Unit, Medical Res. Council, Penarth, Wales) *Br J Cancer* 39(3): 337-341; 1979.

The effects of thymectomy on the induction of mesotheliomas by crocidolite asbestos were studied in Wistar rats. The rats were thymectomized or sham-operated before 4 days of age and then treated with the asbestos (20 mg in physiological saline inoculated into the pleural cavity). Some animals were given three intrapleural injections of carrageenan after asbestos treatment. The carcinogenicity factor (a measure of tumor growth rate) was significantly increased in the thymectomized rats relative to the sham-thymectomized rats, but it was not significantly different from that in the unoperated controls. The carcinogenicity factor was significantly reduced ($p < 0.01$) in the sham-operated rats compared with the intact rats. Intrapleural carrageenan was associated with an 11-fold increase in the carcinogenicity factor relative to the sham-operated rats. There was no significant difference in age at tumor occurrence in any of the groups. The data indicate that thymectomy before the fourth day of age does not alter the carcinogenicity factor of crocidolite, whereas surgical intervention alone at the same age markedly reduces it. 79-2479 Gallium-67 Citrate (⁶⁷GA) Uptake in Benign and Malignant Pleural Disease (Meeting Abstract). (Eng) Sorek, M. (Dept. Oncology, Mount Sinai Medical Center, New York, NY); Teirstein, A. S.; Goldsmith, S. J.; Chahinian, P. *Clin Res* 27(2): 491A; 1979 (no refs)

79-2480 Natural Carcinogenic Products. (Eng) Weisburger, E. K. (NCI, Bethesda, MD 20014) *Environ Sci Technol* 13(3): 278-281; 1979.

Naturally occurring carcinogens produced by plants or by microbes are enumerated along with the species and organs known to be affected by these agents. (7 refs)

79-2481 Carcinogenicity Examination of Betel Nuts and Piper Betel Leaves. (Eng) Mori, H. (Dept. Pathology, Gifu Univ. Sch. Medicine, 40 Tsukasa-machi Gifu 500, Japan); Matsubara, N.; Ushimaru, Y.; Hirono, I. *Experientia* 35(3): 384-385; 1979.

ACI rats were divided into four groups (containing 8-11 males, 8-9 females each) and fed diets containing a dry powder of (1) betel nuts (20% of diet) for 480 days, (2) betel nuts (20%) + lime (1%) for 480 days, or (3) piper betel leaves (20%) for 300-327 days or (4) a normal diet. The betel nuts, betel leaves, and lime are the main ingredients of the betel quid that is chewed by Southeast Asians. Epidermal thickening was frequently observed in the upper digestive tracts of Groups 2 and 3 rats. A forestomach papilloma was seen in one rat in Group 3. The epidermal changes were rarely seen in rats of Groups 1 or 4. One transitional cell carcinoma of the urinary bladder and one myeloid leukemia were detected in Group 1, and one myeloid leukemia was detected in Group 2. These results suggest, but do not demonstrate, the carcinogenicity of chewing betel quid. (14 refs)

79-2482 Inhibition of Chemical Carcinogen-induced Neoplasia by Coumarins and α -Angelicalactone. (Eng) Wattenberg, L. W. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, Minneapolis, MN 55455); Lam, L. K.; Fladmoe, A. V. *Cancer Res* 39(8): 1651-1654; 1979.

Four naturally occurring plant constituents, coumarin (CM), umbelliferone (7-hydroxycoumarin), scopoletin (7-hydroxy-6-methoxycoumarin), and limettin (5,7-dimethoxycoumarin), were studied for their effects on 7,12-dimethylbenz(a)anthracene-induced neoplasia of the Sprague-Dawley rat mammary gland. CM was a moderately potent inhibitor, limettin was less effective, and scopoletin showed only marginal inhibitory activity. Umbelliferone did not inhibit. CM and its three derivatives were also investigated for their effects on benzo(a)pyrene (BP)-induced neoplasia of the ICR/Ha mouse forestomach.

CM inhibited, but the three derivatives did not. Coumaranone and phthalide, two related compounds, were inactive, as were three substituted pyrones included in the study. Four five-membered ring lactones were also investigated. One of these, α -angelicalactone, inhibited BP-induced neoplasia of the mouse forestomach and was more potent in this regard than CM. The other three, γ -valerolactone, L-ascorbic acid, and isocitric lactone, were inactive. Three structure-activity relationships are evident from this study. With the CM's, increased polarity of substituents results in decreasing activity as inhibitors. For both the CM's and the five-membered ring lactones, protic groups, such as hydroxy and carboxy groups, abolish the capacity to inhibit. Although unsaturation in the lactone ring does not always lead to inhibitory activity, the presence of at least one double bond is essential. Thus, the property of inhibition of BP and 7,12-dimethylbenz(a)anthracene is not a general characteristic of all CM's and alicyclic lactones but is restricted to those with specific structural features. (19 refs)

- 79-2483 Testing the Environment for Dispersed Mutagens: Use of Plant Bioconcentrators Coupled with Microbial Mutagen Assays.** (Eng) Barnes, W. S. (Dept. Botany, Univ. Massachusetts, Amherst, MA 01003); Klekowski, E. J. *Environ Health Perspect* 27: 61-67; 1978.

Data on an assay that utilizes certain indigenous or introduced components of an ecosystem to concentrate dispersed mutagens from the environment are presented. Extracts made from these bioconcentrators are fractionated and tested for mutagenic activity in microbial systems. The assay is termed a coupled assay, since it couples an accumulator of environmental mutagens with a microbial system. There are numerous plant and animal species that concentrate toxic substances from the environment; eg, mussels, algae, and aquatic angiosperms such as the water hyacinth. Organisms most widely used to screen for genetic activity are strains of *Escherichia coli* or *Salmonella typhimurium* containing frameshift or base substitution mutations that revert in the presence of mutagens specific for these effects. However, fractions can be tested with a broad range of microbial assays covering numerous genetic end points both with and without mammalian microsomal activation. Compared with physicochemical techniques, the sampling techniques in the coupled assays are simpler and a wider chemical spectrum can be screened. However, there are certain inherent aspects of these procedures that may generate false positives (either the presence of the necessary metabolite in the extract when the microbial test depends on a back mutation system from auxotrophy to prototrophy, or the extraction of an endogenous mutagen) or false negatives (presence of microbial toxins in the extract, inactivation of the mutagen by the bioconcentrator, or selection of a mutagen assay with the wrong genetic end point). In spite

of these obstacles, assays based on bioconcentrators will have a significant role in screening ecosystems. (71 refs)

- 79-2484 Aflatoxin B₁ Mutagenesis, DNA Binding, and Adduct Formation in *Salmonella typhimurium*.** (Eng) Stark, A. A. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA 02139); Essigmann, J. M.; Demain, A. L.; Skopek, T. R.; Wogan, G. N. *Proc Natl Acad Sci USA* 76(3): 1343-1347; 1979.

The quantitative relationship between the binding of aflatoxin B₁ (AFB₁) to *Salmonella typhimurium* strain TM677 DNA, in the form of specific adducts, and forward mutation to 8-azaguanine resistance (8AGR) was studied. *Salmonella* was treated with AFB₁ in liquid suspension culture in the presence of a rat liver postmitochondrial supernatant. A linear relationship was obtained between the induced 8AGR fraction and the concentration of AFB₁. The efficiency of mutagenesis was high: 0.1% of all cells became 8AGR at 0.32 μ M AFB. DNA purified from mutagenized cells was analyzed for AFB₁ adduct formation by high-pressure liquid chromatography after adduct liberation. AFB₁ exposures at 0.16 and 0.32 μ M for 35 min produced 15 and 22 AFB₁-DNA adducts per genome, respectively, and induced 8AGR fractions of 4.9×10^{-4} and 9.6×10^{-4} . Seventy percent of the AFB₁ bound to DNA was identified chromatographically as 2,3-dihydro-2-(N⁷-guanyl)-3-hydroxyaflatoxin B₁, at the two AFB₁ levels used. These findings support the hypothesis of a cause-effect relationship between DNA adduct formation by AFB₁ and mutagenesis and carcinogenesis. The possibility cannot be ruled out, however, that the mutagenic activity of AFB₁ in *Salmonella* results from interactions with macromolecules other than DNA, since the DNA contained only 2% of the total covalently bound AFB₁. - 79-2486 Induction of Both Epoxide Hydratase and a Second Microsomal Membrane Polypeptide by Hepatocarcinogens (Meeting Abstract).** (Eng) Murray, R. K. (Univ. Toronto, Toronto, Ontario M5S 1A8, Canada); Sharma, R. N.; Gurtoo, H. L.; Griffin, M. J.; Cameron, R. G.; Farber, E. *Fed Proc* 38(3, part 2): 660; 1979 (2 refs)

- 79-2487 Conditions for Induction of Bacteriophage from Lysogenic *Bacillus megaterium* with**

Aflatoxin B₁. (Eng) Whittaker, B. L. (Dept. Poultry Science, Ohio State Univ., Columbus, OH 43210); Chipley, J. R. *Appl Environ Microbiol* 37(3): 554-558; 1979.

An attempt was made to determine whether or not aflatoxin B₁ (AFB) was an effective inducing agent for lysogenic bacteria and to characterize some of the parameters involved in induction. A lysogenic strain of *Bacillus megaterium* (NRRL-B-3695) and an indicator strain of this species (NRRL-B-3694) were used. Cultures of the lysogenic strain were incubated for various periods of time in the presence of AFB. Plaque-forming units as well as colony-forming units were then determined. The results indicated that bacteriophage lysogenizing *B. megaterium* could be induced with AFB. The optimum AFB concentration for induction was 25 µg/ml of early-log-phase culture. Evidence suggested that (1) higher concentrations of AFB formed hydrophobic complexes that would not efficiently induce *B. megaterium*; (2) the toxic effect of AFB severely limited the number of cells that could be induced prior to the killing action of the toxin; and (3) AFB concentrations <25 µg/ml were not efficient inducers of bacteriophage production and they did not demonstrate the toxic effect observed at higher concentrations. 79-2488 Investigations of In Vitro Liver Metabolism of Aflatoxin B₁ by the Young Dairy Calf (Meeting Abstract). (Eng) Bodine, A. B. (Clemson Univ., Clemson, SC 29631) *Diss Abstr Int B* 39(8): 3764; 1979 (no refs)

79-2489 Chemical Compounds in Food-producing Animals. Criteria and Procedures for Evaluating Assays for Carcinogenic Residues. (Eng) Gardner, S. (Food and Drug Admin., 5600 Fishers Lane, Rockville, MD 20857) *Fed Regist* 44(55): 17070-17114; 1979.

Procedures and criteria proposed by the Food and Drug Administration to ensure the absence of cancer-causing residues in edible products of animals to which drugs, food additives, or color additives have been administered are detailed. Evaluation of the carcinogenic risk involves a number of steps including threshold assessment (use, residues of toxicological concern, and potential toxicological significance), metabolic studies in target animals to identify residues of concern, chronic toxicity testing, metabolic studies to select marker residues and target tissues (the level of a marker residue in a particular tissue is in a known relationship to the level of the total residue of carcinogenic concern in all edible tissues), evaluation of a compound's effect on pools of carcinogenic or potentially carcinogenic substances endogenous to target animals, and determination of the acceptable level of risk. Procedures

for establishing withdrawal periods, for ensuring compliance, for waiver of requirements, and for implementation are summarized. (79 refs)

79-2490 Preserved Foods as Possible Cancer Hazards: WA Rats Fed Salted Fish Have Mutagenic Urine. (Eng) Fong, L. Y. (Dept. Biochemistry, Univ. Hong Kong, Hong Kong); Ho, J. H.; Huang, D. P. *Int J Cancer* 23(4): 542-546; 1979.

The mutagenicity of foods traditionally and commonly consumed by the southern Chinese, including two samples of dried shrimp and four samples of different species of salted fish, was tested in the *Salmonella typhimurium* microsome mutagenicity assay using tester strains TA98 and TA100. Mutagenic activities toward both tester strains were found in all preparations. In most cases, these activities were enhanced by liver microsome activation. Urine collected from Wistar albino (WA) rats regularly fed salted fish also showed mutagenic activity. The level of this activity decreased markedly when the rats were transferred from a salted fish diet to a Purina rat chow diet. The data suggest that there are mutagenic substances in some preserved Chinese foods. At least one of them, salted fish, has been suspected, based on epidemiological and experimental evidence, of being a possible cocarcinogenic factor in the development of nasopharyngeal carcinoma in the southern Chinese. 79-2491 Pesticides. (Eng) Abdulla, M. (Unit Community Care Sciences, Natl. Board Health and Social Welfare, Dalby, Sweden); Dencker, I.; Haglund, G.; Persson, K.; Norden, A.; von Rosen, G. *Scand J Gastroenterol Suppl* 14(52): 217-222; 1979.

Residue levels of some common pesticides in the normal diet of elderly persons in a region of Sweden were measured and found to be appreciably less than those in many parts of the world. (39 refs)

79-2492 The Effect on Sister-Chromatid Exchanges of Drugs and Dyes by Intercalation and Photoactivation. (Eng) Speit, G. (Institut für Humangenetik und Anthropologie der Universität, D-7800 Freiburg i.Br., W. Germany); Vogel, W. *Mutat Res* 59(2): 223-229; 1979.

Intercalating dyes [acridine orange (AO), proflavin (PF), and methylene blue (MB)] and drugs [chlorpromazine (CPZ), promazine, and chlorprothixene] were tested for their ability to induce sister chromatid exchanges (SCE's) in a clonal derivative of the V79 Chinese hamster cell line with and without photoactivation by visible light. All three

drugs induced SCE's, the frequency increasing at concentrations between 0.25 and 1.0 $\mu\text{g/ml}$ and then leveling off at a nearly twofold increase at concentrations between 1.0 and 5 $\mu\text{g/ml}$. All drugs showed cytotoxic effects, making tests at higher concentrations impossible. Similar dose-effect curves were obtained with the dyes, which caused cytotoxicity and induced SCE's at concentrations 10 times lower than those of the drugs. Visible light alone increased the frequency of SCE's slightly. However, it doubled the toxicity and the effectiveness of PF and AO in inducing SCE's. In contrast, the results obtained with MB and CPZ were similar before and after photoactivation. (23 refs)

- 79-2493 Formation of Nitrosamines from Food Dyes and Effect of Additives Thereon.** (Eng) Banerjee, T. S. (Central Food Lab., Calcutta, India); Roy, B. R. *J Inst Chem (India)* 50(part 3): 134-138; 1978.

The production of nitrosamines by food dyes containing secondary and tertiary amino groups (indigocarmine, Fast Green FCF, Green S, Blue FCF, and Metanil Yellow) was studied. On reaction with sodium nitrite and acid, all five dyes produced nitrosamines, the amounts being greater with the dyes containing tertiary amino groups. Ascorbic acid, glucose, and sodium bisulfite inhibited the reaction, possibly by reduction of nitrous acid. It has been hypothesized that nitrosamines must be transformed into diazoalkanes to be carcinogenic and that this is possible only if both carbon atoms attached to the nitrogen carry hydrogen atoms. Therefore, in view of the structure of the dyes in this study, the nitrosamines produced may not be carcinogenic. (43 refs)

- 79-2494 Order Denying Petition for Food Additive Regulation on Gentian Violet.** (Eng) Luther, L. W. (Bureau Veterinary Medicine, Food and Drug Admin., Dept. Health, Education and Welfare, 5600 Fishers Lane, Rockville, MD 20857) *Fed Register* 44(63): 19035-19038; 1979.

Responses to a petition proposing that food additive regulations be amended to provide for the safe use of 1 lb of a 1.60% gentian violet premix per ton of poultry feed as an aid in controlling fungus and mold growth are presented. The safety of gentian violet as an additive to animal feed has not been established, and there is some evidence that it may be toxic, mutagenic, and carcinogenic to animals. Also, the effectiveness of Gentian Violet in inhibiting mold growth in animal feed has not been established. Furthermore, the environmental impact analysis report as submitted is incomplete, data verifying the chemical identity and composition of the gentian violet proposed for use are lacking, and there are no data demonstrating that the product will possess a uniform identity, strength, quali-

ty, and purity for a given period of time. Thus, the Food and Drug Administration is denying the petition. (39 refs)

- 79-2495 Neoplasms and Pigmentation of Thyroid Glands in F344 Rats Exposed to 2,4-Diaminoanisole Sulfate, a Hair Dye Component.** (Eng) Ward, J. M. (Carcinogenesis Testing Program, Tumor Pathology Branch, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014); Stinson, S. F.; Hardisty, J. F.; Cockrell, B. Y.; Hayden, D. W. *J Natl Cancer Inst* 62(4): 1067-1073; 1979.

The pathology of the thyroid lesions induced in rats by 2,4-diaminoanisole sulfate (2,4-DAAS), a hair dye component, is reported in detail. The compound was fed at dietary levels of 0.12% (low dose) or 0.5% (high dose) to groups of 50 male and 50 female inbred F344 rats for 78 wk. By 107 wk after the initial exposure, 58% of the male rats and 42% of the female rats administered the high dose had thyroid neoplasms, vs only 7%-8% of the controls. Follicular cell carcinomas were the primary type of neoplasm induced. None of the controls had these tumors. The carcinomas were papillary, cystic, or solid, and they were highly invasive locally but did not metastasize. A brown pigment was present as granules primarily in thyroid follicular cells in all exposed rats. The amount of pigment, as determined by an image-analyzing computer, revealed that the cross-sectional area occupied by the pigment granules and the optical density of the granules were dose-related. This pigment may represent a reaction product of 2,4-DAAS and iodine. The manufacturers of human hair dyes have recently agreed to remove 2,4-DAAS from commercial hair dye preparations. (15 refs)

- 79-2496 Determination of Cadmium, Lead and Copper in Wine by Differential Pulse Anodic Stripping Voltammetry.** (Eng) Oehme, M. (Dept. Chemistry, Univ. Oslo, Box 1033 Blindern, Oslo 3, Norway); Lund, W. *Fresenius Z Anal Chem* 294(5): 391-397; 1979.

The simultaneous determination of cadmium, lead, and copper in wine by differential pulse anodic stripping voltammetry at a hanging mercury drop electrode is described. The samples are decomposed in a mixture of sulfuric acid and hydrogen peroxide at 180 C. The procedure was evaluated by recovery tests and compared with other wet digestion methods. Pb levels in 10 wine samples (65-230 ppb) were below the accepted max level, but some wines contained relatively large amounts of Cu (0.08-1.04 ppm). Cd levels were low (1.4-6.6 ppb). (19 refs)

- 79-2497 Ganglioneuroblastoma and Fetal Hydantoin-Alcohol Syndromes.** (Eng) Seeler, R. A. (Div.

Pediatric Hematology, Cook County Hosp., 1825 W. Harrison St., Chicago, IL 60612); Israel, J. N.; Royal, J. E.; Kaye, C. I.; Rao, S.; Abulaban, M. *Pediatrics* 63(4): 524-527; 1979.

A ganglioneuroblastoma developed in a 35-mo-old boy with both the fetal hydantoin (FHS) and fetal alcohol syndromes. The mother had consumed at least a pint of alcohol a day during the pregnancy, and she had been on a regimen of diphenylhydantoin (100 mg 3x/day) until the third or fourth month of pregnancy. Chromosome analysis showed a normal male karyotype. Skeletal survey showed a bilateral absence of the ossification centers of the terminal phalanges of the fifth toes. There were no intracranial calcifications or evidence of bone metastasis. The left kidney was displaced by a suprarenal mass that was identified as a ganglioneuroblastoma. The boy also showed postnatal growth deficiency, mental retardation, fine motor dysfunction, short palpable fissures, pronounced facial hirsutism, metopic ridging, ocular hypertelorism, and a broad nasal bridge. Two other cases of FHS associated with neuroblastoma were reported in 1976. These three cases should establish the relationship between FHS and the development of neural crest tumors, since three such cases should occur by chance only once in 60 yr. The association with tumor has been recognized only in children with the dysmorphic features of FHS. It is not known whether there is an increased risk of malignancy in exposed children without dysmorphic features. (9 refs)

79-2498 Response of the Rat to Saccharin with Particular Reference to the Urinary Bladder. (Eng) Chowanec, J. (Sch. Pathology, Middlesex Hosp. Medical Sch., London, England); Hicks, R. M. *Br J Cancer* 39(4): 355-375; 1979.

Male and female Wistar rats were administered sodium saccharin for life (2 yr), either in their drinking water or diet. The max palatable saccharin dose in the drinking water was 2 g/kg/day and, even then, there was some voluntary restriction of fluid intake in the males. By contrast, 4 g/kg/day was palatable in the diet. Control rats of both sexes received saccharin-free diets and drinking water. Mild urothelial hyperplasias developed by 85 wk in rats of both sexes receiving saccharin in drinking water or diet; the incidence was statistically significant in both the bladders and kidneys of rats receiving the higher dose in the diet, but only in the kidneys of rats receiving the lower dose in the drinking water. Telangiectasia of the *vasa recta* was significant in saccharin-treated rats of both sexes at both doses. Of the three bladder tumors that were seen at 95 or 102 wk, all were in males receiving the higher saccharin dose in the diet. No consistent relationship between bladder epithelial hyperplasias and crystalluria could be demonstrated, although all three bladder tumors were associated with some form of mineralization. The results suggest a particular susceptibility of males to saccharin

treatment. However, rather than initiating carcinogenesis, saccharin may promote or enhance the development of latent tumor cells. (78 refs)

79-2499 Dissociation of Mutagenic from Chemotherapeutic Activities of Drugs (Meeting Abstract). (Eng) Batzinger, R. P. (Johns Hopkins Univ., Baltimore, MD) *Diss Abstr Int [B]* 39(10): 4838; 1979 (2 refs)

79-2500 Concentration and Separation of Arsenic from Polluted Water by Ion Exchange. (Eng) Sandhu, S. S. (Claflin Coll., Orangeburg, SC 29115); Nelson, P. *Environ Sci Technol* 13(4): 476-478; 1979.

A technique for the concentration and separation of arsenic from polluted environmental samples, which contain metal ions reported to interfere with As determination by the silver diethyldithiocarbamate (SDDC) method, is described. Aqueous samples are digested with potassium permanganate and eluted through chromatograph columns packed with Amberlite ion-exchange resin. As retained by the resin is extracted with HCl prior to its determination by the SDDC method. The technique facilitates the quantitative determination of As at levels below 0.005 mg/liter. (18 refs)

79-2501 Concentration and Analysis of Polycyclic Aromatic Hydrocarbons in Water. (Ger) Faltusz, E. (Staatliche Milchwirtschaftliche Lehr- und Forschungsanstalt, Am Maierhof 7, D-7988 Wangen im Allgau, W. Germany) *Fresenius Z Anal Chem* 294(5): 385-390; 1979.

A simple and rapid adsorption method for the concentration and analysis of polycyclic aromatic hydrocarbons (PAH) in water is described. The magnesium salt added to the sample is precipitated, the precipitate is dissolved by ammonium chloride, and the organic substances are extracted with a very small volume of cyclohexane. The PAH are then separated gas chromatographically with the use of an electron-capture detector. (20 refs)

79-2502 Gas-Liquid Chromatographic-Mass Fragmentographic Determination of Low Levels of Diethylcarbonate in Beverages. (Eng) van Lierop, B. H. (Food Inspection Service, Nijenoord 6, Utrecht, Netherlands); Nootenboom, H. *J Assoc Off Anal Chem* 62(2): 253-256; 1979.

Combined gas-liquid chromatography-mass fragmen-

tography was used to determine the levels of diethyl carbonate, an impurity present in diethyl pyrocarbonate (DEPC), in samples of fruit drinks, wine, and beer. DEPC is added to beverages to prevent fermentation. Sixteen of 138 samples had >30 ppb diethyl carbonate. (5 refs)

- 79-2503 Comparison and Evaluation of Some Experimental Designs for Use in Carcinogen Screening.** (Eng) Elashoff, R. M. (Dept. Biomathematics, Sch. Medicine, Univ. California, Los Angeles, CA 90024); Preston, D. L.; Fears, T. R. *J Natl Cancer Inst* 62(5): 1209-1219; 1979.

The development and evaluation of experimental designs for routine in vivo screening of chemicals for potential carcinogenicity are discussed. The current one-stage 50-animal/group screen used by NCI is described, and a two-stage alternative, which would use 35 animals/group is proposed. This alternative allows for retesting of equivocal compounds. The proposed designs were evaluated in terms of sensitivity, specificity, and decision-making using simulated data on 2,000 compounds. Despite the large number of tests made for each compound, the false-positive rate was <0.07 for the current one-stage screen and <0.05 for the proposed two-stage alternative. The two-stage screen, however, would permit 30% more decisions per test period with a savings of 28% in the expected number of animals needed per compound tested. (6 refs)

- 79-2506 Genetic Differences in Metabolism of Polycyclic Aromatic Carcinogens and Aromatic Amines by Mouse Liver Microsomes. Detection by DNA Binding of Metabolites and by Mutagenicity in Histidine-dependent *Salmonella typhimurium* In Vitro.** (Eng) Levitt, R. C. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH,

Bethesda, MD 20014); Pelkonen, O.; Okey, A. B.; Nebert, D. W. *J Natl Cancer Inst* 62(4): 947-955; 1979.

Genetic differences in the DNA binding of carcinogenic (or noncarcinogenic) metabolites in vitro were compared with genetic differences in the mutagenicity of these metabolites in the *Salmonella typhimurium* assay. The metabolism of various carcinogens and other chemicals by genetically regulated increases in cytochrome P₁-450 levels was studied with the use of liver microsomes from 3-methylcholanthrene (3-MC)-treated C57BL/6N and DBA/2N mice. Genetic differences were seen in the DNA binding of metabolites in vitro for dibenz(a,h)anthracene, benz(a)anthracene, benzo(a)pyrene (BP), 3-MC, 7,12-dimethylbenz(a)anthracene (DMBA), 2-acetylaminofluorene, and dopamine (approx in descending order). Any difference for dibenz(a,c)anthracene or ben-zidine was very small. Marked genetic differences were observed in the in vitro mutagenicity assay (with tester strains TA1538, TA98, or TA100) for 6-aminochrysene, dibenz(a,h)anthracene, dibenz(a,c)anthracene, β -naphthylamine, 3-MC, 2-acetylaminofluorene, BP, benz(a)anthracene, and α -naphthylamine (approx in descending order); the difference for DMBA was very small. Therefore, important discrepancies for certain carcinogens existed between genetic differences in metabolites binding to DNA and genetic differences in metabolites causing mutation in the bacterial assay. The data may be useful for future studies with any of these chemicals in the extrapolation of genetic differences observed in vitro to differences in the risk of cancer associated with the *Ah* locus in the intact animal. - 79-2507 In Vitro Mutagenicity Assays of Chemical Carcinogens and Related Compounds with *Salmonella typhimurium*.** (Eng) Simmon, V. F. (Dept. Toxicology, SRI International, Menlo Park, CA 94025) *J Natl Cancer Inst* 62(4): 893-899; 1979.

The mutagenicity of 101 chemical carcinogens and non-carcinogens of various classes was determined in the *Salmonella typhimurium*/microsome assay system with the use of tester strains TA1535, TA1536, TA1537, TA1538, TA98, and TA100. Assays were conducted in the presence and absence of a metabolic activation system prepared from the livers of randomly bred Sprague-Dawley rats that had been pretreated with Aroclor 1254. The test chemicals were incorporated into the agar with the bacteria and the metabolic activation system. Mutagens were defined as chemicals that induced a reproducible dose-related increase in the number of histidine-independent revertants. With the use of these procedures, 65% of the organic carcinogens and 25% of the noncarcinogens were found to be mutagenic. The aromatic amines, polycyclic aromatic hydrocarbons, and alkylating agents had the highest correlation between mutagenicity and carcinogenicity. The nitrosamines and the miscellaneous chemicals had the poorest correlation. (16 refs)

79-2508 Energy-related Pollutants in the Environment: Use of Short-Term Tests for Mutagenicity in the Isolation and Identification of Biohazards. (Eng) Epler, J. L. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Larimer, F. W.; Rao, T. K.; Nix, C. E.; Ho, T. *Environ Health Perspect* 27: 11-20; 1978.

To investigate the potential genetic (and carcinogenic) hazards associated with the developing synthetic fuel technologies, a coupled chemical and biological analysis was made of the products, process streams, and effluents of existing or proposed energy-generating or -conversion systems. One phase of the study deals with known compounds expected to occur in the environment through energy production, conversion, or use; another phase deals with actual samples from existing or experimental processes. To approach the problems inherent in testing large numbers of compounds, a tier system of mutagenicity tests was set up. The *Salmonella* histidine-reversion system is used in the first tier; the standard test for sex-linked recessive lethals in *Drosophila* is used in the second tier; and the specific locus test in the mouse is used in the third tier. The tiered system compared with alternative mutagenicity tests. Data obtained when a group of substituted nitroso compounds were assayed in *Salmonella*, yeast, and *Drosophila* systems are presented. All systems showed a high correlation of mutagenic response with carcinogenicity. The feasibility of applying mutagenicity testing to environmental effluents and crude products from the synthetic fuels technology was tested by screening a condensate sample from an experimental coal gasification process in the *Salmonella* test. The results showed that biological testing can be carried out, but perhaps only with the appropriate analytical separation scheme. The results of comparative studies in other test systems generally validated the results of the initial screening carried out in the *Salmonella* assay. Although the applicability of the *Salmonella* assay results to other genetic assays needs further validation, short-term tests appear to be useful as prescreening devices in testing large numbers of hazardous environmental compounds and complex mixtures. (41 refs)

79-2509 Selection of Carcinogens and Related Compounds Tested for Mutagenic Activity. (Eng) Poirier, L. A. (Lab. Carcinogen Metabolism, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014); Weisburger, E. K. *J Natl Cancer Inst* 62(4): 833-840; 1979.

The rationale for selecting 102 chemical carcinogens and noncarcinogens to be tested for mutagenicity in a National Cancer Institute program to determine the extent of correlation between carcinogenesis and mutagenesis in standard assays is given. The chemicals were divided into five major categories: 37 aromatic amines, 11 polycyclic aromatic hydrocarbons, 8 nitrosamines and nitrosamides, 16 alkylating agents, and a miscellaneous category consisting of 11 heterocyclic compounds, 7 amines, ureas, and

acylating agents, 5 antimetabolites, 4 inorganic chemicals, and 3 promoters. The chemicals were further classified as procarcinogens (requiring metabolic activation to exert their biologic activities), ultimate carcinogens (direct-acting chemicals not requiring metabolic activation), and noncarcinogens (compounds shown to be inactive in one or more adequate carcinogenicity tests). The selection and categorization of the compounds are documented by an extensive bibliography. (168 refs)

79-2510 In Vitro Assays for Recombinogenic Activity of Chemical Carcinogens and Related Compounds with *Saccharomyces cerevisiae* D3. (Eng) Simmon, V. F. (Dept. Toxicology, SRI International, Menlo Park, CA, 94025). *J Natl Cancer Inst* 62(4): 901-909; 1979.

The utility of *Saccharomyces cerevisiae* D3 as a prescreen for a broad spectrum of potential carcinogens was tested with the use of a standard protocol that was maintained throughout the experiments. A total of 101 carcinogens, noncarcinogens, metals, and promoters representing a wide variety of chemical classes was tested to determine whether they increased mitotic recombination in *S. cerevisiae* D3. A metabolic activation system prepared from homogenates of livers from rats that had been pretreated with Aroclor 1254 (a mixture of polychlorinated biphenyls) was incorporated in the assay. All of the 20 ultimate carcinogens and 18/48 procarcinogens increased mitotic recombination. Of the noncarcinogens, 6/21 also increased mitotic recombination. An improved metabolic activation procedure appeared to be required to increase the probability of detecting procarcinogens by this method. The carcinogens thioacetamide, natulan, auramine, safrole, and 1'-hydroxysafrole increased mitotic recombination in *S. cerevisiae* D3 (the last compound was marginally positive), but they were negative in assays with *Salmonella typhimurium*. (22 refs)

79-2511 Mutagenic Activity of Chemical Carcinogens and Related Compounds in the Intraperitoneal Host-mediated Assay. (Eng) Simmon, V. F. (Life Sciences Div., Dept. Toxicology, SRI International, Menlo Park, CA, 94025); Rosenkranz, H. S.; Zeiger, E.; Poirier, L. A. *J Natl Cancer Inst* 62(4): 911-918; 1979.

The mutagenicities of 79 carcinogens, noncarcinogens, and structurally related compounds toward *Salmonella typhimurium* strains TA1530, TA1535, and TA1538 and toward *Saccharomyces cerevisiae* D3 were investigated in the ip host-mediated assay. Fewer than half of the carcinogens were mutagenic toward the *Salmonella* strains. The insensitivity of the system was most marked with the aromatic amine and polycyclic hydrocarbon procarcinogens. Under the test conditions, < 10% of the carcinogens showed clear mutagenic activity toward *S. cerevisiae* D3. However, none of the noncarcinogens was significantly mutagenic toward

either *S. typhimurium* or *S. cerevisiae* D3. Overall, the ip host-mediated assay does not seem suitable for routine preliminary screening of large numbers of potential carcinogens. The median lethal doses to mice of 46 compounds were determined. (23 refs)

79-2512 Evaluation of the Mutagenicity and DNA-modifying Activity of Carcinogens and Noncarcinogens in Microbial Systems. (Eng) Rosenkranz, H. S. (Dept. Microbiology, New York Medical Coll., Valhalla, NY, 10595); Poirier, L. A. *J Natl Cancer Inst* 62(4): 873-892; 1979.

The predictive value of two short-term microbial assays in identifying potential carcinogens was evaluated with the use of 99 chemical carcinogens and noncarcinogens. The mutagenicity of the chemicals was determined in a standard *Salmonella typhimurium* (ST) assay with strains TA1535 and TA1538; their DNA-modifying capacity was determined with normal and DNA polymerase-deficient *Escherichia coli* (EC) strains. The chemicals consisted of: alkylating agents (15); nitrosamines, hydrazines, and related substances (8); heterocyclics (10); aromatic amines (36); polycyclic aromatic hydrocarbons (11); amides, ureas, and acylating agents (7); antimetabolites (5); inorganics (4); and promoters (3). Twenty-one compounds were known noncarcinogens, 21 were ultimate carcinogens, and 45 were procarcinogens. Of the noncarcinogens, 35% were positive in the ST system, 30% were positive in the EC system, and 25% were positive in both systems. Of the ultimate carcinogens, 100% were mutagenic in EC, 79% in ST, and 79% in both systems. Of the procarcinogens, 52% and 67% were positive in the ST and EC assays, respectively, and 48% were positive in both systems. A tabulation of the combined data for ultimate carcinogens and procarcinogens indicated that 77% of the compounds were mutagenic: 61% and 74% in the ST and EC assays, respectively, and 59% in both assays. For prescreening procedures with microbial assays, it is suggested that ST strains TA98 and TA100 be included and that the standard EC DNA polymerase-deficient assay be run in tandem with the ST mutagenicity assay. When the standard EC DNA polymerase-deficient assay does not give interpretable results because of the lack of growth inhibition zones, a modified assay with the use of liquid suspension should be performed. (59 refs)

79-2513 Initial National Cancer Institute Studies on Mutagenesis as a Prescreen for Chemical Carcinogens: An Appraisal. (Eng) Poirier, L. A. (Nutrition and Metabolism Section, Lab. Carcinogen Metabolism, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD, 20014); de Serres, F. J. *J Natl Cancer Inst* 62(4): 919-926; 1979.

A National Cancer Institute (NCI) collaborative study of mutagenesis as a prescreen for chemical carcinogens was evaluated. The initial objectives were to develop a list of carcinogens and related compounds that would be tested and to select mutagenic systems offering the greatest promise of discriminating between carcinogens and noncarcinogens of widely varying chemical structures. The efficacy of several in vitro and in vivo assays to detect carcinogens from a list of 102 compounds was determined. *Salmonella typhimurium* and polymerase A-deficient *Escherichia coli* in vitro were the most effective systems studied. Together, they detected 82% of the organic carcinogens tested. Potential prescreening systems that were thought to be currently insufficiently sensitive for the routine screening of potential carcinogens included (1) the development of resistance to thymidine overloading, methotrexate, or cytosine arabinoside by L5178y mouse lymphoma cells; (2) genetic lesions (eg, mitotic recombination in *Saccharomyces cerevisiae* D3; (3) ip host-mediated assays using *S. typhimurium*, *S. cerevisiae* and L5178y cells; and (4) thymidine uptake as a reflection of DNA repair. The present evaluation of the NCI collaborative study has revealed a correlation between carcinogenic and mutagenic activity. (39 refs)

79-2514 Production of a Mutagen from Ponceau 3R by a Human Intestinal Anaerobe. (Eng) Hartman, C. P. (Bethesda Res. Labs., Rockville, MD, 20850); Andrews, A. W.; Chung, K. T. *Infect Immun* 23(3): 686-689; 1979.

The metabolic reduction of the azo dye Ponceau 3R by the human intestinal bacteria *Fusobacterium* sp. 2 was studied. The reaction was characterized by a lag period of 30 min followed by a 96% reduction within 90 min and 100% reduction within 3 hr. One of the metabolites obtained was 2,4,5-trimethylaniline (41.9%), which was mutagenic in the Ames *Salmonella* mammalian microsome mutagenicity assay when activated by rat liver S9 preparations. Also obtained in large quantity was 2,4-dimethylaniline (38.4%), indicating that a substantial part of Ponceau 3R is the closely related dye Ponceau 2R, which differs in structure from Ponceau 3R in that it lacks a ring methyl group. Although 2,4-dimethylaniline is mutagenic in the Ames assay in quantities > 250 µg, such large quantities were not generated under the conditions studied. None of the other dimethylanilines isolated from the extract of the reduced dye showed any mutagenicity in quantities up to 1,000 µg. (9 refs)

79-2515 In Vitro Metabolic Activation of Chemical Carcinogens to Mutagens and Its Relationship to Cancer Induction in Vivo (Meeting Abstract). (Eng) Brusick, D. J. (Litton Bionetics, Inc., 5516 Nicholson Lane, Kensington, MD, 20795). *In Vitro* 15(3): 208; 1979. (no refs)

79-2516 Aryl-Monoalkyl and Cyclic Triazenes: Direct-acting Mutagens. (Eng) Thomas, H. F. (Dept. Medical Genetics, Univ. Wisconsin, Madison, WI, 53706); Brown, D. L.; Hartman, P. E.; White, E. H.; Hartman, Z. *Mutat Res* 60(1): 25-32; 1979.

The mutagenicity of a linear aryl-monoalkyl triazene, methyl-p-tolyl triazene (MTT), and a cyclic triazene, δ^2 -triazoline, for *Salmonella typhimurium* and for *Hemophilus influenzae* cell-free DNA was tested. Both triazenes were direct-acting mutagens. MTT caused reversion of the *hisG46* base-substitution mutation but not of the *hisD3052* frameshift mutation. The strains carrying the *hisG46* mutation were equally sensitive to mutagenesis, independent of genetic background. Mutation frequency induced by MTT was strongly enhanced by liquid preincubation before plating. It was decreased by the presence of caffeine in the plating medium and increased by a pool of common L-amino acids. This is the first report of mutagenicity by a cyclic triazene. (33 refs)

79-2517 The Mutagenic Action of Nitroimidazoles. IV. A Comparison of the Mutagenic Action of Several Nitroimidazoles and Some Imidazoles. (Eng) Voogd, C. E. (Lab. Chemotherapy, Natl. Inst. Public Health, P.O. Box 1, Bilthoven, The Netherlands); Van Der Stel, J. J.; Jacobs, J. J. *Mutat Res* 66(3): 207-221; 1979.

The mutagenicity of 51 imidazoles was determined in fluctuation tests with *Klebsiella pneumoniae* as the test organism and in the Ames test with *Salmonella typhimurium* TA100 as the tester strain. Of the 33 nitroimidazoles tested, 31 were mutagenic for *K. pneumoniae*, whereas only 2/18 imidazoles without a nitro group were mutagenic. All eight nitroimidazoles tested in the Ames assay were mutagenic for *S. typhimurium*. Regarding the methylnitroimidazoles, mutagenic activity was increased when a methyl group was present on the atom next to that with a nitro group in the imidazole nucleus. Mutagenic activity was decreased when there was an unsubstituted atom between the atoms with the methyl and nitro groups. For molecules with a more complex chemical structure, no clear relationship existed between chemical structure and mutagenicity. Also, there was no direct relationship between antimicrobial action, growth inhibition, and mutagenicity. The possible existence of nitroimidazole derivatives with strong antimicrobial but weak mutagenic actions cannot be excluded. (27 refs)

79-2518 Comparison of the Genetic Activity of 5-Nitroimidazole Derivatives in *Escherichia coli*, *Neurospora crassa*, *Saccharomyces cerevisiae* and *Drosophila melanogaster*. (Eng) Mohn, G. R. (Environmental Mutagenesis Branch, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC, 27709); Ong, T. M.; Callen, D. F.; Kramers, P. G.; Aaron, C. S. *J Environ Pathol Toxicol* 2(3): 657-670; 1979.

Four 5-nitroimidazoles, including metronidazole [MNZ: 1-(2-hydroxyethyl)-2-methyl-5-nitroimidazole], 6-(2-dimethylamino-ethoxy)-2-(5-nitro-1-methyl-2-imidazolylmethylene)-1-tetralone sulfate (compound 2), 3-(5-nitro-1-methyl-2-imidazolyl)methyleneamino-5-morpholinomethyl-2-oxazolidone hydrochloride (compound 3), and 1-(3-morpholinopropyl)-2-(5-nitro-1-methyl-2-imidazolyl)benzimidazole (compound 4), were tested for mutagenic activity in several assay systems. MNZ was moderately mutagenic toward *Escherichia coli*. Compounds 2 and 3 were strongly mutagenic even at concentrations that did not inactivate the colony-forming ability of the cells. Compound 4 showed no effect toward *E. coli*. Similar results were obtained with *Neurospora crassa*, *Saccharomyces cerevisiae*, and *Drosophila melanogaster*, with compound 2 exhibiting a higher effect than compound 3. These biological effects were explained partly on the basis of differences in chemical structure. The findings indicate that conjugation of an unsaturated center with the 5-nitro grouping via the carbon at position 2 enhances mutagenicity and that attachment of an aromatic ring directly to position 2 of the 5-nitroimidazole nucleus reduces the mutagenic potential. (29 refs)

79-2519 Isolation and Identification of the Metabolite of N-(5-Nitro-2-furfurylidene)-3-amino-2-oxazolidone (Furazolidone). (Eng) Tatsumi, K. (Faculty Pharmaceutical Sciences, Kyushu Univ., 3-1-1 Maidashi, Higashi-ku, Fukuoka, 812, Japan); Ou, T.; Yamada, H.; Yoshimura, H.; Koga, H.; Horiuchi, T. *J Pharmacobio Dyn* 1(4): 256-261; 1978.

The in vitro and in vivo metabolites of furazolidone [N-(5-nitro-2-furfurylidene)-3-amino-2-oxazolidone] were isolated, and the mutagenicities of one metabolite and the parent compound for *Salmonella typhimurium* strain TA100 were determined. Incubation of furazolidone with milk xanthine oxidase yielded two reduction products. The first was identified as 3-(4-cyano-2-oxobutylideneamino)-2-oxazolidone (COO), and the structure of the second was not identified. COO was also isolated from the urine of male rabbits given a single 100-mg/kg dose of furazolidone po. Furazolidone was highly mutagenic for *S. typhimurium*, whereas COO was nonmutagenic. The data suggest that COO is not an active metabolite of furazolidone. (26 refs)

79-2520 Electrochemical Properties of Polycyclic Compounds Studied by the Polarographic Method in Anhydrous Systems. VI. The Influence of Proton-Donor on Reduction of Carcinogenic Aromatic Hydrocarbons in Anhydrous Environment. (Eng) Vachalkova, A. (Cancer Res. Inst., Slovak Acad. Sciences, 880 32 Bratislava, Czechoslovakia); Podany, V.; Bahna, L. *Neoplasma* 25(6): 679-684; 1978.

The electrochemical behavior of a series of carcinogenic and

noncarcinogenic polycyclic aromatic hydrocarbons (PAH) was studied in an anhydrous environment (in dimethylformamide or dimethyl sulfoxide) in the presence of a proton donor (phenol). Based on changes in polarographic behavior induced by phenol, the PAH were divided into three groups. The Group 1 PAH were noncarcinogenic or only marginally carcinogenic. They responded to increasing phenol concentrations with higher diffuse current values for the first and second polarographic waves; the values of the half-wave potentials remained practically unchanged. Group 2 was characterized by high carcinogenicity. With increasing phenol concentration, a diffuse and irreversible new wave appeared between the two original waves of these compounds. The new wave increased at the expense of the second original wave. Group 3 contained only 1,2,5,6-dibenz(a)anthracene, which shows relatively high carcinogenicity. With the addition of phenol to this compound, the original second wave increased at the expense of the third wave until the latter disappeared at the half-wave potential value of the original second wave. This new polarographic wave was of a diffuse and irreversible character. Thus, the polarographic method described can be used to distinguish carcinogenic from noncarcinogenic PAH. (7 refs)

- 79-2521 Tobacco-specific Nitrosamines: Occurrence, Formation, Carcinogenicity, and Metabolism.** (Eng) Hecht, S. S. (Div. Environmental Carcinogenesis, Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Chen, C. H.; Hoffmann, D. *Acc Chem Res* 12(3): 92-98; 1979.

The occurrence, formation, carcinogenicity, and metabolic activation of tobacco-specific nitrosamines are reviewed. Both N'-nitrosanornicotine (NNN) and 4-(N-methyl-N-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK), but not 4-(N-methyl-N-nitrosamino)-4-(3-pyridyl)butanal (NNA), have been detected in tobacco and tobacco smoke. NNN has been proved to be carcinogenic in mice, rats, and hamsters. In a comparison bioassay in strain A mice, NNK was more carcinogenic than NNN, but NNA did not show significant activity. Nitrosoanabasine was somewhat carcinogenic in rats and noncarcinogenic in hamsters. In vitro and in vivo experiments demonstrated that both NNN and N-nitrosopyrrolidine undergo metabolic α -hydroxylation in the rat, and it is likely that α -hydroxylation is the critical step in the metabolic activation of these compounds. Since NNN and NNK are derived predominantly from nicotine by nitrosation during the curing and smoking of tobacco, human exposure might be reduced by appropriate management of the curing processes. Enzymes mediating the metabolic activation and detoxification of tobacco-specific nitrosamines might be induced or inhibited by environmental modifiers. (70 refs)

- 79-2522 The Fate of Intratracheally Instilled ^3H -Styrene Oxide in the Isolated Perfused Rat Lungs.**

(Eng) Uotila, P. (Dept. Physiology, Univ. Turku, SF-20520 Turku 52, Finland). *Res Commun Chem Pathol Pharmacol* 23(3): 561-573; 1979.

The metabolism and covalent binding of intratracheally instilled ^3H -styrene oxide (100 nanomoles) in the isolated perfused lungs of control and cigarette smoke-exposed male Wistar rats were investigated. After the instillation, the lungs were perfused for 16 min and the nonrecirculating perfusate was collected in two fractions: 0-8 min and 8-16 min. About 40% of the instilled dose was in the 0- to 8-min perfusion medium, mainly in the form of unmetabolized styrene oxide. However, the radioactivity in the 8- to 16-min perfusion medium and lung tissue itself was mainly in the form of water-soluble metabolites, probably glutathione conjugates. The amount of styrene glycol was very small. Exposure of the rats to cigarette smoke had no effect on the metabolism of styrene oxide or on the amount of the compound that was covalently bound to the protein and nucleic acid fractions of the perfused lungs. (26 refs)

- 79-2523 Comparison of the Induction by Cigarette Smoke Condensates of Sister-Chromatid Exchanges in Chinese Hamster Cells and of Mutations in *Salmonella typhimurium*.** (Eng) De Raat, W. K. (Div. Technology, Society TNO, P.O. Box 217, Delft, Netherlands). *Mutat Res* 66(3): 253-259; 1979.

Cigarette smoke condensates (CSC's) prepared from three European brands of cigarette were tested for the induction of sister chromatid exchanges (SCE's) in Chinese hamster ovary cells and for mutations in *Salmonella typhimurium* TA98 and TA100. Brand A (low-tar brand) produced 21 mg CSC/3 cigarettes, brand B 55 mg/3 cigarettes, and brand C 69 mg/3 cigarettes. Rat liver microsomal (S9) fractions were prepared from rats pretreated with Aroclor 1254, phenobarbital, or 3-methylcholanthrene or from untreated rats. The results of the SCE tests showed that an SCE-inducing compound was present in the CSC's. None of the four metabolic activation systems enhanced the amount of SCE-inducing compound. The three CSC's did not differ much in their capacity to induce SCE. In the *Salmonella* test, revertants were produced only when S9 fractions from rats treated with inducers of the enzyme systems necessary for metabolic activation were added. TA98 was much more sensitive than TA100. Apparently, the SCE and *Salmonella* tests are sensitive to different components of CSC. (13 refs)

- 79-2524 Liver and Lung Cell-mediated Mutagenesis of V79 Cells with Chemical Carcinogens (Meeting Abstract).** (Eng) Langenbach, R. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE, 68105); Tompa, A.; Kuszynski, C.; Kennedy, S.; Huberman, E. *In Vitro* 15(3): 209; 1979. (no refs)

79-2525 Application of In Vitro Transformation and Metabolism to the Study of Cocarcinogenesis (Meeting Abstract). (Eng) Nesnow, S. (US Environmental Protection Agency, Research Triangle Park, NC, 27711); Leavitt, S. *In Vitro* 15(3): 208; 1979. (no refs)

79-2526 Effects of Caffeine on Sister-Chromatid Exchanges (SCE) In Vivo. (Eng) Basler, A. (Dept. Human Genetics and Anthropology, Universitätsstr. 1, Geb 23.12, D-4000 Dusseldorf 1, W. Germany); Bachmann, U.; Roszinsky-Kocher, G.; Rohrborn, G. *Mutat Res* 59(2): 209-214; 1979.

Chinese hamsters were treated with caffeine (2 doses of 20, 100, 200, or 400 mg/kg given 24 hr apart, by stomach tube) and/or benzo(a)pyrene (BP: 2 doses of 450 mg/kg ip) or cyclophosphamide (CP: 2 doses of 5 mg/kg ip) and the effects of these agents on the frequency of sister chromatid exchanges (SCE's) and chromosome aberrations in bone marrow cells was determined. The SCE frequency increased with increasing dose of caffeine up to 2 x 200 mg/kg, which resulted in a mean number of 6.20 SCE's/metaphase; the mean number of SCE's/metaphase was 10.57 after BP and 12.35 after CP. Simultaneous po treatment with caffeine reduced the frequency of SCE's induced by CP or BP. Nonsignificant increases in metaphases with structural chromosome aberrations were induced by BP or caffeine; simultaneous administration of the two agents caused a synergistic effect. (18 refs)

79-2527 Bioassay Procedure for the Detection of Mutagenic Metabolites in Human Urine with the Use of Sister Chromatid Exchange Analysis. (Eng) Guerrero, R. R. (Pasadena Foundation Medical Res., 99 N. El Molino Ave., Pasadena, CA, 91101); Rounds, D. E.; Hall, T. C. *J Natl Cancer Inst* 62(4): 805-809; 1979.

A sensitive, reproducible, short-term bioassay system for the detection of activated mutagenic metabolites in urine from humans exposed to promutagens is described. Human diploid fibroblasts were grown in medium containing 5%-20% urine from 8 smokers, 7 nonsmokers, and 2 individuals undergoing cyclophosphamide (CP) chemotherapy for cancer (5.0 and 7.5 mg/kg/wk iv, respectively). The cells were then subjected to sister chromatid exchange (SCE) analysis. Activated CP metabolic products in urine specimens produced up to a ten-fold increase in SCE's over preinjection SCE levels for the same individuals. Linear dose-response curves over a 5%-20% urine concentration range were obtained with cells grown in urine specimens from the nonsmokers and the cigarette smokers. This test system proved to be sensitive to ambient exposure levels of environmental mutagens, and it demonstrated that urine from smokers was significantly more mutagenic than was urine from nonsmokers. Replicate experiments showed highly reproducible SCE values for each individual as well as for av SCE values for each group of

subjects. The ability of this bioassay system to detect trace mutagenic activity in human urine reproducibly makes it an attractive choice for the monitoring of humans who have been exposed to environmental and/or industrial mutagens. (30 refs)

79-2528 Accessibility of Deoxyribonucleic Acid in Chromatin to the Covalent Binding of the Chemical Carcinogen Benzo(a)pyrene. (Eng) Jahn, C. L. (Dept. Bacteriology and Immunology, Univ. North Carolina at Chapel Hill, Sch. Medicine, Chapel Hill, NC); Litman, G. W. *Biochemistry* 18(8): 1442-1449; 1979.

The role of chromatin structure in the binding of benzo(a)pyrene (BP) to DNA was investigated. A model system utilizing rat liver microsomes to activate [³H]BP in the presence of calf thymus nuclei was used to examine the ability of BP to bind regions of DNA that differ in their accessibility in chromatin. [³H]BP-modified nuclei were digested with staphylococcal nuclease and DNase I, and the specific activity (counts/minute of [³H]BP/absorbance at 260 nanometers of DNA) of the DNA remaining undigested was determined. Both enzymes resulted in characteristic changes in specific activity as a function of digestion. No changes occurred during digestion of isolated [³H]BP-DNA, and BP had no effect on the kinetics of digestion of DNA or nuclei, indicating that the specific activity changes seen in nuclear digests were due to preferential binding to DNA in regions of chromatin differing in enzyme susceptibility. The nucleosomal sites of [³H]BP binding were determined by electrophoretic analysis of the resistant DNA and by examining the specific activity as a function of digestion of (1) nucleosome multimers isolated by sucrose gradient sedimentation of [³H]BP-modified nuclei partially digested with staphylococcal nuclease and of (2) monomer subfractions obtained by KCl precipitation of H1-containing monomers. In addition, the distribution of [³H]BP in fragments obtained from a DNase I digest of nuclei was compared with that of an isolated monomer fraction. These data led to the conclusion that BP binds to the spacer region and the outermost portions of the nucleosome core. (41 refs)

79-2529 Analysis of Prehistoric Levels of Benzo(a)pyrene in Permafrost Soil. (Rus) Il'nitskii, A. P. (Cancer Res. Center, Moscow, USSR); Vinogradov, V. N.; Riabchun, V. K.; Mishchenko, V. S.; Gvil'dis, V. Iu.; Chernen'kii, B. I.; Belitskii, G. A.; Shabad, L. M. *Dokl Akad Nauk SSSR* 245(1): 254-257; 1979.

In an attempt to estimate the natural level of carcinogenic polycyclic aromatic hydrocarbon (PAH) during prehistoric geological periods, levels of benzo(a)pyrene (BP) were analyzed in samples of permafrost soil. Spectrofluorometric assay of soil samples taken at depths ranging from 0.06-0.16 m (active layer) to 0.80-0.90 m ($\geq 10,000$ yr old) confirmed the presence of BP in all layers of permafrost. The natural

level of BP ranged from 1 to 5 $\mu\text{g/kg}$ of dry soil. This level was comparable to the current background level of PAH and, thus, could be due to the existence of natural sources of these compounds. (9 refs)

- 79-2530 Binding of Benzo(a)pyrene into Lung and Thymocyte Nuclear Fractions.** (Eng) Blazsek, I. (Dept. Medical Chemistry, Univ. Helsinki, Siltavuorenpenger 10 A, 00170 Helsinki 17, Finland); Vauhkonen, M.; Hemminki, K. *Res Commun Chem Pathol Pharmacol* 23(3): 611-626; 1979.

The in vitro binding of ^3H -benzo(a)pyrene to rat lung cells and thymocytes was studied. In most lung cell fractions, the specific radioactivity of protein exceeded that of RNA and DNA, but in the chromatin fraction, RNA was most actively labeled. The labeling of DNA in the matrix fraction was threefold that in the chromatin fraction, and the matrix sediment proteins were more actively labeled than the proteins of other fractions. A high level of binding to RNA was observed in the thymocytes. Again, binding to protein was greater in the matrix fraction than in the other fractions. Nonhistones were more actively labeled than histones, the difference being 30-fold in the lung fractions and 10-fold in the thymocyte fractions. Highly radioactive peaks were associated with matrix sediment proteins with approx mol wts of 55,000 and 130,000 daltons. (29 refs)

- 79-2531 Metabolism of Benzo(a)pyrene to Reactive Intermediate(s) via Prostaglandin Biosynthesis.** (Eng) Sivarajah, K. (Lab. Pulmonary Function and Toxicology, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Anderson, M. W.; Eling, T. E. *Life Sci* 23(26): 2571-2578; 1978.

The oxidation of benzo(a)pyrene (BP) and other polycyclic aromatic hydrocarbons to electrophilic metabolites during the formation of prostaglandins (PG) and thromboxanes from arachidonic acid (AA) by guinea pig lung microsomal protein was examined. In the presence of NADPH or AA, electrophilic metabolites of [^{14}C]-BP were generated that were nonextractable from microsomal protein and thus assumed to be covalently bound. The total amount of BP metabolized in the presence of NADPH was 2-2.5 times the amount of BP metabolized in the presence of AA. Only 4%-5% of BP metabolized by the NADPH-mediated mixed-function oxidase system was covalently bound, whereas 12%-15% of the BP metabolized in the presence of AA was covalently bound to tissue protein and DNA. Quinones were the major metabolites produced by the AA-dependent system, and dihydrodiols were the major metabolites formed by the NADPH-dependent system. 7,12-Dimethylbenz(a)anthracene and 7,8-BP dihydrodiol, but not 3-hydroxy-BP, were also oxidized by PG synthetase to reactive metabolites. (27 refs)

- 79-2532 Effects of a Cytochrome P-450 Inhibitor on Covalent Binding of [^3H]Benzo(a)Pyrene in Nil Cell Fractions.** (Eng) Sloane, N. H. (Dept. Microbiology and Molecular Genetics, Harvard Medical Sch., Boston, MA, 02115); Chu, L. N.; Amos, H. *IRCS Med Sci (Cancer)* 7(2): 81; 1979.

1-Benzylimidazole (BI) inhibited the covalent binding of ^3H -benzo(a)pyrene to both the nuclear and cytoplasmic fractions of Nil cells. Second cycle cells initially exposed to the chemicals and subsequently grown in their absence showed a preferential concentration of BI in the nuclear fraction. (4 refs)

- 79-2533 Metabolism of Lipid Peroxides During Chemical Carcinogenesis.** (Rus) Lankin, V. Z. (Inst. Chemical Physics, Moscow, USSR); Poliakov, V. M.; Arkhangel'skaia, A. V.; Gurevich, S. M. *Biull Eksp Biol Med* 87(3): 270-273; 1979.

The metabolism of lipid peroxides during chemical carcinogenesis was studied in random-bred albino rats that were inoculated sc with benzo(a)pyrene (BP: 5 mg in 0.5 ml of olive oil). Rats were sacrificed at various times after BP injection, and phospholipid levels and enzymatic and nonenzymatic activities of phospholipid peroxidation in the liver and tumor tissue were assessed. BP caused a marked increase in the level of lecithin and cephalin in the liver microsomes and mitochondria that was max at 14 wk, the time of tumor appearance. Tumor development was associated with a drastic decrease in phospholipid levels. These levels were significantly lower in the tumor tissue than in the liver (5.0-5.5 mg/g and 25.2 mg/g, respectively). In contrast, glutathione peroxidase activity was significantly greater in the tumor (46.7 IU at 16 wk, 69.8 IU at 20 wk, and 67.4 IU at 24 wk than in the liver (37.0 IU). These findings indicate that the detoxification of phospholipid peroxides was significantly more effective in the tumor tissue than in the liver. (14 refs)

- 79-2534 A New Assay for Glutathione S-Transferase Using (^3H)-Benzo(a)pyrene 4,5-Oxide as Substrate. Inducibility by Various Chemicals in Different Rat Tissues Compared to that of Aryl Hydrocarbon Hydroxylase and Epoxide Hydratase.** (Eng) Van Cantfort, J. (Laboratoire de Chimie Medicale, Institut de Pathologie, B-4000 Sart-Tilman, Liege 1, Belgium); Manil, L.; Gielen, J. E.; Glatt, H. R.; Oesch, F. *Biochem Pharmacol* 28(4): 455-460; 1979.

A new assay for glutathione S-transferase (GST) uses ^3H -benzo(a)pyrene 4,5-oxide (^3H -BP 4,5-oxide) as a substrate. It is performed under conditions that are optimal with respect to both the pH and the concentration of the two substrates (2mM glutathione and 80 μM BP 4,5-oxide). The substrate and product are separated by a differential extraction, and the radioactivity in the aqueous fraction is counted by liquid

scintillation spectrometry. Other than a trace of ^3H -BP 4,5-oxide, the aqueous fraction contained only one labeled product that was identified as a glutathione conjugate. The assay was used to determine the effect of cigarette smoke inhalation on GST activity in liver, kidney, and lung and to compare this effect with that of the drug metabolizing enzyme inducers phenobarbital (PB), 3-methylcholanthrene (3-MC), and 16 α -cyanopregnenolone and with the effect on aryl hydrocarbon hydroxylase (AHH) and epoxide hydratase (EH). Liver AHH activity was enhanced by the three inducers, but only 3-MC and cigarette smoke significantly induced enzyme activity in lung and kidney. EH activity was induced by 16 α -cyanopregnenolone and PB in liver but not in other tissues. GST activity was also inducible, but the inductions were quantitatively weaker than those of the other two enzyme activities and were limited to the liver. These results indicate that GST is insensitive to the administration of chemicals to animals, and they suggest that the role of this enzyme in the metabolism of polycyclic hydrocarbons might be very limited. (25 refs)

79-2535 Identification of Benzo(a)pyrene Metabolites by Gas Chromatograph-Mass Spectrometer.

(Eng) Takahashi, G. (Dept. Pathology, Chest Disease Res. Inst., Kyoto Univ., Sakyo-ku 606, Kyoto, Japan); Kinoshita, K.; Hashimoto, K.; Yasuhira, K. *Cancer Res* 39(5): 1814-1818; 1979.

Combined gas chromatography-mass spectrometry was used in an attempt to separate and identify benzo(a)pyrene (BP) and 38 of its metabolites (12 phenols, 6 quinones, 6 dihydroxyl compounds, 7 diols, 4 stereoisomeric tetraols, 2 diol epoxides, and 1 epoxide). All derivatives, after being trimethylsilylated, were developed on Dexsil-300 and OV-1 columns. The 7 diols and 4 stereoisomeric 7,8,9,10-tetraols were separated successfully, but not the 12 phenols. The 8- and 11-isomers appeared separately but the other 10 isomers formed 3 peaks on the OV-1 column. The five phenols previously reported to be present in animal tissue were applied to the Dexsil-300 column. The 6-, 7-, and 9-phenols were separated, but the 1- and 3-phenols eluted together. The quinones were converted to related dihydroxyl derivatives under silylation. The chromatographic separation of 4/6 dihydroxyl derivatives was successful on the OV-1 column, but the 6,12- and 7,10-isomers formed in a single peak. The two diol epoxides were converted to 7,8,9-trihydroxy-7,8-dihydro-BP under silylation. Therefore, it was impossible to identify the diol epoxides themselves. However, the presence of stereoisomeric 7,8,9,10-tetraols and/or 7,8,9-trihydroxy-7,8-dihydro-BP strongly suggests that the test material contains diol epoxides. The mass spectra and retention times of all the BP derivatives studied are given. (26 refs)

79-2536 Formation of DNA Adducts in 10T1/2 Mouse Embryo Fibroblasts Incubated with Benzo(a)-

pyrene or Dihydrodiol Oxide Derivatives. (Eng) Brown, H. S. (Inst. Cancer Res., Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Jeffrey, A. M.; Weinstein, I. B. *Cancer Res* 39(5): 1673-1677; 1979.

The extent of DNA binding and the types of adducts formed when confluent cultures of the mouse embryo fibroblast cell line 10T1/2 were exposed to radioactive benzo(a)pyrene (BP) or 7,8-dihydroxy-9,10-epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene (BPDE) were analyzed. The cells metabolized BP to its diastereoisomeric 7,8-dihydrodiol-9,10-oxides, (\pm)-7 β ,8 α -dihydroxy-9 α , 10 α -epoxy-7,8,9,10-tetrahydro-BP (BPDE I) and (\pm)-7 β ,8 α -dihydroxy-9 β ,10 β -epoxy-7,8,9,10-tetrahydro-BP (BPDE II), which formed covalent adducts with cellular DNA. Detailed analysis by high-pressure liquid chromatography indicated that a deoxyguanosine adduct, N²-(10S-[7R,8S,9R-trihydroxy-7,8,9,10-tetrahydrobenzo(a)pyrene]yldeoxyguanosine, was the predominant DNA adduct formed in cells exposed to BP. This adduct is also the major one found in human tissues exposed to BP. Exposure of cells to BPDE I and BPDE II, rather than to BP, produced several additional DNA adducts. During a 68-hr posttreatment incubation, about 50%-70% of the adducts were removed from the cellular DNA. No major differences between the relative rates of excision from cellular DNA of the individual BPDE I and BPDE II adducts were found. These results provide evidence that when 10T1/2 cells are exposed to BP, there is stereoselective synthesis and covalent binding of BPDE mainly to the N² group of deoxyguanosine. This similarity with results obtained in human tissues makes the 10T1/2 cell an attractive model system for studying the action of BP and related polycyclic hydrocarbons. (36 refs)

79-2546 Induction and Properties of Aryl Hydrocarbon Hydroxylase in Bovine Pancreatic Ducts. (Eng) Kahng, M. W. (Dept. Pathology, Univ. Maryland Sch. Medicine, 31 S. Greene St., Baltimore, MD, 21201); Jones, R. T.; Trump, B. F. *J Natl Cancer Inst* 62(5): 1251-1255; 1979.

The inducibility and characteristics of aryl hydrocarbon hydroxylase (AHH) in cultured bovine pancreatic ducts were

studied fluorometrically. AHH was present and inducible in all pancreatic ducts exposed to 20 μ g benz(a)anthracene (BA)/ml medium. AHH activity in the control tissue ranged from 1.0 to 3.0 units (U)/mg DNA, whereas the activity in the BA-treated tissue was 4.2-28.5 U/mg DNA. The induction ratio, defined as the ratio of the activity of enzyme preparations from BA-treated ducts to control enzyme activity, ranged from 5 to 18. After 12 hr of BA exposure, AHH activity in the treated tissue was 12 times that in the control tissue, and it continued to increase to 15, 19, and 31 times that in the control tissue at 24, 48, and 72 hr, respectively. The BA-induced AHH activity had a broad pH optimum between 7.1 and 7.7, and max activity was found at pH 7.4. The AHH activity was linear with respect to incubation time up to 30 min. A study was also made of the effect of benzo(a)-pyrene concentration on BA-induced AHH activity. The apparent Michaelis constant for the substrate was 0.5 μ M, and the max velocity was 8.6 U/mg DNA. BA-induced AHH activity was inhibited 65% by 100 μ M 7,8-benzoflavone, whereas control enzyme activity was stimulated 100% by the same concentration of 7,8-benzoflavone. (15 refs)

79-2547 Relationship Between Amount and Type of Dietary Fat in Promotion of Mammary Carcinogenesis Induced by 7,12-Dimethylbenz[a]anthracene. (Eng) Hopkins, G. J. (Dept. Clinical Biochemistry, Flinders Medical Center, Bedford Park, S. Australia 5042, Australia); Carroll, K. K. *J Natl Cancer Inst* 62(4): 1009-1012; 1979.

The relationship between the amount and type of dietary fat in the promotion of 7,12-dimethylbenz(a)anthracene (DMBA)-induced mammary carcinogenesis was investigated in female Sprague-Dawley rats. The rats were fed semipurified diets containing various fats, either alone or in combination, to provide different amounts of dietary fat and linoleic acid. One week before commencing the diets, each rat received an intragastric dose of 5 mg DMBA. Rats fed diets containing mixtures of 3% sunflower seed oil and 17% tallow or coconut oil developed twice as many tumors as those fed 3% sunflower seed oil or 20% of either saturated fat alone. Tumor yields in the rats fed the mixed-fat diets were comparable to those in rats fed a 20% lard diet, which provided about the same amount of linoleic acid. No further increase in tumor yield was observed in rats fed a 20% sunflower seed oil diet that contained more than five times as much linoleic acid. These results show that a certain amount of polyunsaturated fat, as well as a high level of dietary fat, is required to promote mammary carcinogenesis. (21 refs)

79-2548 Non-random Duplication of Chromosome 15 in Murine T-Cell Leukemias Induced in Mice Heterozygous for Translocation T(14:15)6. (Eng) Wiener, F. (Dept. Tumor Biology, Karolinska Institutet, S-104 01

Stockholm 60, Sweden); Spira, J.; Ohno, S.; Haran-Ghera, N.; Klein, G. *Int J Cancer* 23(4): 504-507; 1979.

The chromosome constitution of 7,12-dimethylbenz(a)anthracene (DMBA)-induced T-cell leukemias in C57BL x CBAT6T6 F₁ mice was studied. The CBAT6T6-derived chromosome T(14;15)6 was regularly duplicated, whereas the C57BL-derived normal chromosome 15 was only present in one copy. It was concluded that the gene(s) that tends to duplicate in parallel with the neoplastic transformation of a prothymocyte to an overt leukemic cell has a greater chance of duplicating and/or may have a stronger promoting effect on leukemogenesis if located on the CBA-derived, structurally rearranged T(14;15)6 than the corresponding gene(s) located on the C57BL-derived normal chromosome 15. (11 refs)

79-2549 Ultrastructural Alterations in Experimental Lingual Leukoplakia and Carcinoma. (Eng)

Marefat, M. P. (Dept. Oral Medicine and Oral Pathology, Harvard Sch. Dental Medicine, 188 Longwood Ave., Boston, MA 02115); Albright, J. T.; Shklar, G. *Oral Surg* 47(4): 334-342; 1979.

Epidermoid carcinomas, preceded by dysplastic leukoplakic lesions, were produced on the right lateral borders of the tongues of 12 male and 12 female Syrian hamsters by the application of 9,10-dimethyl-1,2-benz(a)anthracene (DMBA: 0.5% soln in acetone, 3x/wk) after the area had been scratched with a root canal broach. Animals were killed at 12-13 wk and at 15-16 wk after the start of treatment. Electron microscope studies of both the dysplastic leukoplakic lesions and the well-differentiated epidermoid carcinomas revealed clumping of the tonofilaments and widening of the intercellular spaces in addition to the cellular pleomorphism, altered nuclear-cytoplasmic ratio, and prominent nucleoli observed with the light microscope. In the carcinomas, there were variations in the morphology of the mitochondria, with tubular forms in evidence. The basal lamina in the carcinomas was discontinuous. Pseudopodia arising from basal cells were seen in areas of basal lamina discontinuity. (30 refs)

79-2550 Differential Rotational Mobility of a Membrane-bound Fluorochrome in Cell Types of Increasing Oncogenic Potential. (Eng) Monti, J. A. (Univ. Alabama in Birmingham, Medical Center, Birmingham, AL 35294); Sarraf, A. M.; Christian, S. T.; Saxholm, H. J. *Arch Biochem Biophys* 193(2): 496-501; 1979.

The interaction of the fluorescent phospholipid 4-nitrobenzo-2-oxa-1,3-diazole(aminocaproyl)-phosphatidylcholine NBD-PC, which was used as an extrinsic membrane probe, with mouse embryo C3H/10T1/2 clone

8 (10T1/2) cells and 10T1/2 cells transformed by 7,12-dimethylbenz(a)anthracene (DMBA: Types I-III) or 3-methylcholanthrene (3-MC: Type III) was determined. Specifically, differences in the fluorescence polarization and temperature-dependent emission intensity of incorporated NBD-PC among the various cells were compared. The effects of temperature on the emission intensity of membrane-bound NBD-PC differed for the 10T1/2 cells and the chemically transformed Type I (nononcogenic), Type II (moderately oncogenic), and Type III (highly oncogenic) cells. The behavior of NBD-PC bound to Type III cells transformed by DMBA and 3-MC was similar. The rotational mobility of the membrane-bound fluorochrome increased in the order: 3-MC-Type III > DMBA-Type III > Type II > Type I > 10T1/2. There were significant differences in NBD-PC polarization values between the 10T1/2 cells and the transformed cells, but there were no statistically significant differences in polarization values among the different transformed cells. The data suggest that the dynamic properties of the plasma membranes are sufficiently different for normal and chemically transformed cells to be differentiated on this basis. (36 refs)

79-2551 Suppressive Effect of 3-Methylcholanthrene on Phagocytic Activity of Mouse Peritoneal Macrophages for *Torulopsis glabrata*. (Eng) Tewari, R. P.

(Dept. Medical Sciences, Southern Illinois Univ. Sch. Medicine, Springfield, IL 62708); Balint, J. P.; Brown, K. A. *J Natl Cancer Inst* 62(4): 983-988; 1979.

The effect of methylcholanthrene (3-MC) on the phagocytic activity of C3H and CFW mouse peritoneal macrophages for *Torulopsis glabrata*, an organism occasionally seen as an opportunistic fungal infection in cancer patients, was investigated. Macrophages were maintained in glass scintillation vials or on cover slips in Leighton tubes with the use of Hanks' balanced salt soln plus 30% horse serum. Graded amounts of 3-MC (0, 1, 5, 10, 25, 50, or 100 µg/ml) were incorporated into the medium, and the macrophages were parasitized with viable cells of *T. glabrata*. Macrophages from C3H mice, a strain highly susceptible to 3-MC carcinogenesis, were more prone to the suppressive effect of 3-MC than were the macrophages from CFW mice, a relatively resistant strain. A significant suppressive effect on the phagocytosis of macrophages from C3H mice was observed with 5 µg/ml 3-MC, whereas up to 50 µg/ml did not alter the phagocytic activity of CFW macrophages. However, 100 µg/ml also suppressed the phagocytosis of CFW macrophages. Suppression of C3H macrophage phagocytosis was observed after 6 hr exposure to 3-MC, whereas a similar effect on CFW macrophages was seen after 12 hr. Treatment with 100 µg/ml 3-MC impaired the fungicidal activity of both C3H and CFW macrophages. These results indicate that there is a correlation between the suppressive effect of 3-MC on macrophage activity and the strain susceptibility of mice to chemical carcinogenesis. (38 refs)

- 79-2552 Rimantadine but Not Amantadine Protects Fischer Rat Embryo Cells from Transformation Induced by 3-Methylcholanthrene or Benzo(a)pyrene.** (Eng) Price, P. J. (Center Disease Control, 1600 Clifton Road, N.E., Atlanta, GA 30333); Mansfield, J. I.; Hassett, C. M. *In Vitro* 15(2): 82-85; 1979.

The in vitro oncogenic potential and the ability to protect cells from polycyclic hydrocarbon-induced transformation of the antiviral drugs amantadine hydrochloride (AM) and rimantadine hydrochloride (RM) were tested using a serial line of Fischer rat embryo cells (F1706) that previously had been shown to be an accurate indicator of chemicals known to be oncogenic in animal studies. Neither compound (0.5 µg/ml RM, 1.0 or 2.0 µg/ml AM) was found to have transforming activity. At these levels, which were slightly toxic, RM, but not AM, protected the cells from transformation induced by 3-methylcholanthrene (0.1 or 0.2 µg/ml) and benzo(a)pyrene (0.5 µg/ml). (11 refs)

- 79-2553 Effects of Donor Age on Neoplastic Transformation of Adult Mouse Bladder Epithelium In Vitro.** (Eng) Summerhayes, I. C. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Franks, L. M. *J Natl Cancer Inst* 62(4): 1017-1023; 1979.

An attempt was made to demonstrate the effects of aging on neoplastic transformation in long-term primary cultures of the bladder, an organ in which an age-associated tumor incidence has been found in humans. Neoplastic transformation of C57BL/1crf-a' mouse bladder epithelium was induced in long-term primary cultures by a single 24-hr treatment with 7,12-dimethylbenz[a]anthracene on day 2 of culture. Transformed foci appeared earlier (40-60 days) and at a higher frequency (28%) in cultures from old donors (28-30 mo), compared with 100 days and 0.9% in cultures from young adult donors (5-7 mo). After transplantation into syngeneic mice, transformed cells produced carcinomas. Spontaneous epithelial transformation occurred in dimethyl sulfoxide-treated old cultures after the same time interval (40-50 days) as in the carcinogen-treated cultures, but at a lower frequency (5.3%). Spontaneous epithelial transformation did not occur in cultures from young donors. (18 refs)

- 79-2554 Immunity to a 3-Methylcholanthrene-induced Fibrosarcoma in the C57BL/6 Mouse: In Vivo Analysis by the Adoptive Tumor Neutralization Test.** (Eng) Poupon, M. F. (Laboratoire d'Immunochimie, Institut de Recherches Scientifiques sur le Cancer, B. P. No. 8, 94800 Villejuif, France); Lespinats, G.; Kolb, J. P.; Payelle, B. *J Natl Cancer Inst* 62(4): 989-994; 1979.

The adoptive tumor neutralization test (modified Winn

test) was used to study antitumor immunity in C57BL/6 mice made immune to a 3-methylcholanthrene (3-MC)-induced fibrosarcoma (MC-B6-1). Spleen cells from mice immunized against this tumor partially or completely protected recipient mice from the growth of MC-B6-1 tumor cells when both spleen and tumor cells were inoculated sc. In the case of partial immunity, the tumor growth rate was decreased only during the first, and not the second, phase of tumor development. Protection in the Winn test was a specific phenomenon between MC-B6-1 and a second MCA-induced fibrosarcoma (MC-B6-2). T cells were required for successful immunity, with neither B cells nor macrophages from normal or immunized mice provided any protection against tumor growth. The degree of protection increased with the number of transferred immune spleen cells and with the number of challenges received by the immunized mice. The protective effect was abrogated when the immune spleen cells were exposed to 1,000 R radiation. When immune spleen cells were injected at a distance from the tumor cells, no protection was conferred. However, 49% of these mice were protected against a subsequent challenge. Immune spleen cells did not protect nude mice from the growth of the MC-B6-1 fibrosarcoma. The results indicate that it is possible to demonstrate an antitumor reaction to a chemically induced tumor by the Winn test. (21 refs)

- 79-2555 Effect of Carrageenan on the Non-specific Resistance of Mice to Injected Syngeneic Tumour Cells, Alone or in Mixtures.** (Eng) Wu, R. L. (Dept. Bacteriology, Univ. Sydney, Sydney, Australia); Kearney, R. *Br J Cancer* 39(3): 241-246; 1979.

The mechanisms of nonspecific resistance to two syngeneic methylcholanthrene-induced fibrosarcomas (H-1 and H-2) were investigated using inbred male CBA/H/WEHI mice. Sc inoculation of 0.05×10^5 H-1 or H-2 cells produced tumors in a small number of normal mice, whereas the same number of cells mixed with 10^6 viable, nonreplicating, mitomycin C-treated tumor cells (MCT cells) produced tumors in all normal animals. The effect was reduced when the MCT cells were heat-killed or freeze-thawed, and tumor growth was completely inhibited when latex particles were mixed with the graft. It is likely that the latex particles were toxic for the cells. Carrageenan pretreatment (3 consecutive daily ip doses of 0.5 mg) significantly enhanced the growth of H-1 cells alone, but it had no effect on the growth of MCT-H-1 grafts. Inoculation of MCT-H-1 cells ip did not enhance the growth of sc inoculated H-1 cells. The results support the concept of a nonspecific macrophage "surveillance" system that appears to be crucial in controlling tumor growth, since it determines the establishment of small numbers of tumor cells while they can still be easily destroyed. - 79-2556 Mutagenesis of Human Cells by 3-Methylcholanthrene.** (Eng) Curren, R. D.

(Dept. Biochemical Oncology, Microbiological Assoc., 5221 River Rd., Bethesda, MD 20016); Homer, C. J.; Price, P. J.; Freeman, A. E. *Mutat Res* 60(1): 109-113; 1979.

The mutagenicity of 3-methylcholanthrene (3-MC: 10 µg/ml) for cultures of human foreskin epithelial cells mixed with xeroderma pigmentosum (XP) fibroblasts derived from a female patient was studied. High mutagenicity was observed in these cultures. Similar results were obtained in other experiments with lower doses of 3-MC and with benzo(a)pyrene. Mutant clones that showed resistance to 6-thioguanine or ouabain (OUA) retained their resistant phenotype even during growth in the absence of the selective agent. All five of the OUA-resistant clones had a male karyotype and a wild-type UV-sensitivity, indicating that they were not derived from the extremely UV-sensitive female XP cells. Thus, the induced mutants must have originated from the foreskin explants. It is suggested that the skin epithelial cells metabolized 3-MC to mutagenic products and that the XP cells may have served merely as nonspecific stabilizers of the culture conditions, permitting survival of the small mutant epithelial population. 79-2557 Biochemical Characterization of Alien H-2 Antigens Expressed on a Methylcholanthrene-induced Tumor. (Eng) Rogers, M. J. (Lab. Cell Biology, NCI, Bethesda, MD 20014); Appella, E.; Pierotti, M. A.; Invernizzi, G.; Parmiani, G. *Proc Natl Acad Sci USA* 76(3): 1415-1419; 1979.

Alien H-2 antigens expressed on a methylcholanthrene-induced tumor (C-1) of BALB/c (H-2d) origin were characterized. Membranes or purified antigens from C-1 tumor cells were used to inhibit the precipitation of highly purified H-2a by various alloantisera. The membranes completely inhibited the precipitation of an authentic H-2a molecule, especially by antisera against private specificity 23, indicating that a structural antigen identical to normal H-2Kk is expressed on the C-1 tumor. The alien H-2 molecule was expressed in very small amounts on the membranes of C-1 tumor cells, having a specific activity 1/10 that of H-2Kk antigens on normal cells. Like normal H-2 antigens, the alien antigens have a mol wt of 48,000, are glycoproteins, and are noncovalently bound to β_2 -microglobulin. They differ from normal H-2 antigens in their susceptibility to papain digestion, behavior during gel filtration, and overall stability. Both genetic and epigenetic mechanisms have been suggested to explain the appearance of previously unexpressed phenotypes. Present evidence seems to favor a derepression mechanism for the alien H-2 molecule. A direct mutation of the H-2 gene could cause the structural differences seen in the alien H-2 molecule by affecting the primary structure. Alternatively, the post-translational modification apparatus of the cell might be haplotype specific, so that an H-2Kk molecule would be incorrectly processed in an H-2d cell. (31 refs)

79-2558 Early Influences of the Tumor Promoter 12-O-Tetradecanoylphorbol 13-Acetate (TPA) but Not of 4-O-Methyl-TPA on the Cell Cycle of Hela Cells (Meeting Abstract). (Eng) Kinzel, V. 79-2561 Inhibition of Epidermal Growth Factor Binding to Surface Receptors by Tumor Promoters. (Eng) Brown, K. D. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Dicker, P.; Rozengurt, E. *Biochem Biophys Res Commun* 86(4): 1037-1043; 1979.

The effect of the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) on the binding of radiolabeled epidermal growth factor (EGF) to surface receptors was investigated. Unlabeled EGF [0-20 nanograms (ng)/ml] and TPA (0-1,000 ng/ml) produced a potent, dose-dependent inhibition of [125]EGF (2 ng/ml) binding to Swiss mouse 3T3 cells. The inhibition of radiolabeled EGF binding by TPA was competitive, with no change in max binding capacity but with an approx 10-fold decrease in apparent binding affinity. At 25 ng/ml [125]EGF, the inhibition of binding by 100 ng/ml TPA was completely abolished. EGF inhibited radiolabeled EGF binding at 0 or 37°C, whereas TPA was inhibitory only at 37°C. The inhibitory effect of EGF was rapidly reversed when it was removed from the binding medium, whereas the effect of TPA persisted after its removal. The inhibition of binding was 52% in cells pretreated with saturating concentrations of EGF and 63% in nonpretreated cells, which suggests that TPA and EGF interact with different binding sites. This finding was further supported by ex-

periments in which TPA and EGF triggered biological responses in a synergistic manner. Treatment of 3T3 cells with TPA concentrations as high as 1 $\mu\text{g/ml}$ for 8 hr did not reduce the max binding capacity, but treatment with 2 ng/ml EGF caused a 50% decrease in this value. This indicates that TPA, in contrast to EGF, does not induce "down-regulation" of EGF receptors. The results suggest that TPA does not bind directly to EGF receptors. (19 refs)

79-2564 Modulation of Plasminogen Activator Synthesis in Chick Embryo Fibroblasts by Cyclic Nucleotides and Phorbol Myristate. (Eng) Wilson, E. L. (Dept. Clinical Science and Immunology, Medical Sch., Univ. Cape Town, Cape Town, South Africa); Reich, E. *Cancer Res* 39(5): 1579-1586; 1979.

The effects of phorbol-12-myristate-13-acetate (PMA) and a temperature-sensitive Rous sarcoma virus (ts-68) on plasminogen activator (PA) synthesis by chick embryo fibroblasts (CEF) were studied. Intracellular PA showed a dose- and duration-dependent increase in response to PMA. PMA also increased PA levels in ts-68-infected cells at both the permissive (37 C) and non-permissive (41 C) temperatures, the inductive effects of PMA and the effects of the shift to 37 C being synergistic. Viral transformation lowered the threshold concentration for a response to PMA. The transcriptional events required for PA induction were evident within < 1 hr, and translation was effective by 2 hr. Actinomycin D pretreatment (1 $\mu\text{g/ml}$) blocked the inducing and synergizing effect of PMA on PA synthesis in ts-68-infected CEF at both 37 and 41 C; blocked the inducing and synergizing effect of the sarcoma transformation, irrespective of any preexisting enzyme induction by PMA; and blocked the deinduction of PMA- or virus-determined enzyme levels regardless of the presence or absence of either inducing stimulus. The PA induced by PMA did not differ from that induced by ts-68. PA induction was strongly but reversibly inhibited by exposure of the CEF to AMP or cholera toxin. However, many of the morphological changes accompanying transformation were

not affected by concentrations of cyclic nucleotides that suppressed PA production. Thus, the two phenomena are at least partially independent expressions of transformation in this system. (39 refs)

79-2565 Reversible Inhibition by Retinoids of 3-Methylcholanthrene-induced Neoplastic Transformation in C3H/10T1/2 Clone 8 Cells. (Eng) Merriman, R. L. (Dept. Experimental Therapeutics, Grace Cancer Drug Center, Roswell Park Memorial Inst., New York State Dept. Health, Buffalo, NY); Bertram, J. S. *Cancer Res* 39(5): 1661-1666; 1979.

Cultured C3H/10T1/2 clone 8 mouse embryo fibroblasts were used to study the effects of retinoids on 3-methylcholanthrene (3-MC)-induced neoplastic transformation. At concentrations that did not affect cell survival (0.005-0.5 $\mu\text{g/ml}$), retinyl acetate inhibited 3-MC-induced transformation. Complete inhibition of transformation was observed when 3-MC-treated cells were continuously treated with retinyl acetate (0.1 $\mu\text{g/ml}$) starting 7 days after 3-MC exposure (2.5 $\mu\text{g/ml}$; 24 hr). A brief exposure to retinyl acetate (0.5 mg/ml) on days 7-14 after 3-MC treatment caused a 70% inhibition of transformation, and delaying retinyl acetate exposure up to 3 wk after 3-MC still decreased transformation by 80%. Nontoxic concentrations of retinol and retinal were approx equal in potency to retinyl acetate. The inhibition of neoplastic transformation by retinoids was fully reversible on maintaining initiated cultures for 3-5 wk in drug-free medium. Growth of three established transformed C3H/10T1/2 clone 8 cell lines in the presence of normal cells was not inhibited by 1- $\mu\text{g/ml}$ doses of retinyl acetate or retinol. Thus, in extension of the in vivo studies, it was shown that retinoids inhibit chemically induced neoplastic transformation in cultured mouse fibroblasts and, furthermore, that this inhibition is not related to toxicity. The results indicate that retinoids delay the progression of preneoplastic cells to fully neoplastic cells. (47 refs)

79-2566 Retinoid Inhibition of Carcinogen-induced Transformation in Cryopreserved Golden Syrian Hamster Embryo Cells (Meeting Abstract). (Eng) Traul, K. A. (Pfizer Inc., Maywood, NJ, 07607); Nanna, U.; Wolff, J. S.; Jensen, K. E. *In Vitro* 15(3): 218; 1979. (no refs)

79-2567 Role of Vitamin A in Chemical Carcinogenesis in the Rat Mammary Gland. (Rus) Khandudza, K. L. (Dept. Biophysics, State Univ., Moscow, USSR); Esakova, T. D.; Tarusov, B. N. *Biull Eksp Biol Med* 87(3): 273-275; 1979.

The effect of large po doses of vitamin A on the concentration of 7,12-dimethylbenz(a)anthracene (DMBA) in various or-

gans and tissues was studied in female Wistar rats. Animals received 150,000 IU vitamin A po for 3 days or 250,000 IU for 5 days; control rats received 1.25 ml of corn oil for 5 days. The rats were then inoculated iv with a lipid emulsion of DMBA (2 mg) and sacrificed 10 min or 4, 5, or 6 hr later. At 10 min after DMBA administration, the max concentration of DMBA was detected in the liver, followed by the adrenals, spleen, kidneys, blood, and mammary gland. The DMBA concentration decreased with time in all organs but the mammary gland. Vitamin A decreased the level of DMBA in all organs and in the blood, increased its rate of metabolism, and decreased the level of lipid-soluble DMBA metabolites (the decrease depended on the dose of vitamin A). 79-2568 Tumor Prevention by Vitamin A: In Vitro Studies with Cultured Human Fibroblasts. (Ger)

Kohl, F. V. (I. Medizinische Universitäts-Klinik Hamburg-Eppendorf, Martinistrasse 52, D-2000 Hamburg 20, W. Germany); Rudiger, H. W. *J Cancer Res Clin Oncol* 93(2): 149-160; 1979.

The effects of vitamin A palmitate (VAP), all-trans-retinoic acid (RA), and Ro 10-9359 [ethyl-all-trans-9-(4-methoxy-2,3,6-trimethylphenyl)-3,7-dimethyl-2,4,6,8-nonatetraenoate] on the metabolism of ³H-labeled benzo(a)pyrene were studied in normal diploid human fibroblast cultures. All three compounds caused a concentration-dependent inhibition of the metabolism of BP into active water-soluble metabolites. The concentrations necessary for 50% inhibition were approx 110 µg/ml for VAP, 12.5 µg/ml for Ro 10-9359, and 6.25 µg/ml for RA. The binding of BP metabolites to DNA was also reduced considerably by all three substances. In another experiment, VAP reduced ³H-leucine incorporation to the fibroblasts from 100% to 77%. The inhibiting effect of VAP on the overall protein synthesis of the fibroblasts was less than one-third of that produced by cycloheximide and actinomycin D. The inhibition by the three substances of the formation of water-soluble metabolites was due to a preferential inhibition of the de novo synthesis of BP-metabolizing enzymes, and not to direct inhibition of these enzymes. The findings indicate that the protective effect of vitamin A against certain carcinogens is based on its ability to inhibit activation of the procarcinogen. (33 refs)

79-2569 The Role of Vitamin A and Ascorbic Acid in Relation to Respiratory System Cancers (Meeting Abstract). (Eng)

Lopez-S, A. (Dept. Medicine, Louisiana State Univ. Sch. Medicine, New Orleans, LA); Yates, B.; Johnson, W. D.; Nze, R. *Clin Res* 27(2): 553A; 1979. (no refs)

79-2570 Radiorespirometric Analysis of Glucose Metabolism During the Feeding with 3'-Methyl-4-(dimethylamino)azobenzene in Rat. (Eng) Koji-

ma, S. (Faculty Pharmaceutical Sciences, Teikyo Univ., Suarashi 1091-1, Sagamiko-machi, Tsukui-gun, Kanagawa 199-01, Japan); Shiki, Y.; Kubodera, A. *Radioisotopes* 28(2): 78-83; 1979.

Glucose metabolism was analyzed by a radiorespirometric technique during the administration of 3'-methyl-4-(dimethylamino)azobenzene (3'-Me-DAB) to male Donryu rats. The rats were given a diet containing 0.06% 3'-Me-DAB for 30 wk starting at age 5 wk. Glucose(U-¹⁴C) was given ip (2.5 µCi), and the differential respiratory ¹⁴CO₂ radioactivity was detected continuously for 2 hr. The results of this assay were correlated with δ-fetoprotein (AFP) levels and glycolytic enzyme activities. The peak time (PT: the time when respiratory ¹⁴CO₂ radioactivity reached a max) occurred at 4 wk after 3'-Me-DAB feeding, and the peak height (PH: max radioactivity at PT) was reached at 4-5 wk. This coincided with the appearance of AFP at 3-6 wk. AFP was not detected at 7-10 wk, but it reappeared from the 11th wk onward. After 3'-Me-DAB administration, hexokinase activity decreased up to the 3rd wk, increased during the 4th wk, and returned to control levels at the 6th wk. Pyruvate kinase activity was inhibited immediately after 3'-Me-DAB feeding, but it recovered to control levels at the sixth wk. In tumor-bearing rats, hexokinase and phosphofructokinase activities were lower than those in control rats, but pyruvate kinase activity was twice that in controls. These results suggest that the changes in PT could be related to the activation of hexokinase, followed by activation of the direct oxidative pathway for the conversion of glucose. (27 refs)

79-2571 Reactivity of the Liver to Glucocorticoids During Chemical Hepatocarcinogenesis. (Rus)

Me-chitov, V. I. (Lab. Tumor Biochemistry, Cancer Res. Center, Moscow, USSR); Adler, V. V.; Shapot, V. S. *Biull Eksp Biol Med* 87(3): 270-279; 1979.

Wistar rats with a transplanted Zajdela hepatoma and Wistar rats that were kept on a diet containing 3-methyl-4'-dimethylaminoazobenzene were subjected to partial hepatectomy. One hr after surgery rats were inoculated ip with the glucocorticoid dexamethasone (1 mg/100 g), and 1 hr prior to sacrifice they were inoculated with ³H-thymidine (100 µCi/rat). Dexamethasone inhibited ³H-thymidine incorporation in both the normal hepatocytes and the primary hepatoma cells. Tyrosine aminotransferase inducibility was retained in the hepatoma cells, but hormonal induction of tryptophan pyrrolase was lost. (14 refs)

79-2572 Nitroxide Radicals Generated from Carcinogenic Aminoazo Dyes During Their Metabolism In Vivo and in Enzymatic System In Vitro. (Eng)

Kimura, T. (Biophysics Div., Natl. Cancer Center Res. Inst., Tokyo 104, Japan); Kodama, M.; Nagata, C. *Biochem Pharmacol* 28(4): 557-560; 1979.

The type of nitroxide radical formed from aminoazo dyes during their metabolism by rats and in an enzymatic system *in vitro* is described. 3'-Methyl-N,N-dimethyl-4-aminoazobenzene (3'-methyl-DAB) was incubated with liver microsomes from methylcholanthrene (MC)-treated rats. After incubation, electron spin resonance (ESR) measurement detected a free radical with a signal consisting of six hyperfine splittings. A much larger ESR signal having the same hyperfine structure was observed when 3'-methyl-DAB was replaced by 3'-methyl-N-methyl-4-aminoazobenzene (3'-methyl-MAB). The same ESR signal was also observed when DAB or MAB was incubated with liver microsomes, but the signals were smaller than those of the 3'-methyl substitutes. Comparison of those ESR signals with those generated by authentic samples indicated that the free radical generated enzymatically from 3'-methyl-DAB (or -MAB) was a nitroxide radical. The same type of free radical was also detected *in vivo*. After *po* administration of 3'-methyl-DAB to rats, the livers were removed and extracted with benzene. The ESR signal of the extract was the same as that observed in the *in vitro* experiment. The role of the nitroxide radical in carcinogenesis of aminoazo dyes is not known. However, the finding that the proximate form of aminoazo dyes are easily converted to the nitroxide radical *in vivo* suggests a causal role for this radical in aminoazo dye carcinogenesis. (9 refs)

- 79-2573 Carcinogenic Azo Dyes. IX. Detection of New Metabolites of 3'-Methyl-4-(dimethylamino)azobenzene in Rat Bile.** (Eng) Mori, Y. (Gifu Coll. Pharmacy, Mitahora-higashi 5-6-1, Gifu 502, Japan); Hori, T.; Toyoshi, K.; Horie, M. *J Pharmacobio Dyn* 1(3): 192-201; 1978.

Metabolites appearing in the bile of male Wistar rats administered a *po* dose of 3'-methyl-4-(dimethylamino)azobenzene (3'-Me-DAB; 45 mg/kg) were studied by the ion cluster technique using a mixture of unlabeled and deuterated compounds. The major metabolites appeared to be 3'-carboxyaminoazo dyes and their azo reduced compounds and 3-amino-6-hydroxytoluene and 3-aminobenzyl alcohol and their N-acetylated compounds. Other metabolites were 3'-Me-4-aminoazobenzene (3'-Me-4-AB), 3'-CHO-AB, 3'-CHO-4-(methylamino)azobenzene (3'-CHO-MAB), 3'-Me-MAB, 3'-Me-4'-OH-AB, 3'-Me-4'-OH-MAB, 3'-Me-4'-OH-DAB, 3'-CH₂OH-MAB, 3'-CH₂OH-DAB, 3'-CH₂OH-AB, 3'-Me-4'-OH-AB-NAc, 3-aminobenzaldehyde and its N-acetylated metabolite, 3'-Me-N-OH-AB, and 3'-Me-4-nitroazobenzene. The parent compound, 3'-Me-DAB, was hardly excreted in the bile. This is the first documentation of the occurrence of oxidative metabolism at the ring methyl group of 3'-Me-DAB in the rat. (11 refs)

- 79-2574 Histochemical Comparison of Focal Losses of RNase and ATPase Activities in Preneoplastic Rat Livers.** (Eng) Daoust, R. (Institut du Cancer de Montre-

al, Centre Hospitalier Notre-Dame, 1560 est rue Sherbrooke, Montreal, P.Q., Canada H2L 4M1). *J Histochem Cytochem* 27(2): 653-656; 1979.

To assess the significance of enzyme-deficient foci as putative premalignant lesions, parallel histochemical analyses of RNase and ATPase activities were carried out in serial sections of livers from male Wistar rats fed 4-dimethylaminoazobenzene (DAB; 0.06% of a basal low-protein diet). The RNase activity of the centrilobular liver parenchyma was markedly increased in animals given the basal diet without DAB; ATPase activity was not altered significantly. The cirrhotic liver parenchyma observed after 30 days of DAB feeding showed intense RNase and ATPase activities, whereas the trabecular tissues showed no RNase but high ATPase activity. After 60 days, some areas of the regenerating parenchyma were RNase- and ATPase-negative, and the hepatocytes of the hyperbasophilic foci and hepatocellular carcinomas that developed after 90 days were consistently deficient in RNase and ATPase activities. The RNase and ATPase activities of the regenerating livers of untreated hepatectomized rats were essentially normal. The results indicate that groups of hepatocytes show a simultaneous loss of nuclease and canalicular ATPase activities at early stages of hepatocarcinogenesis. These foci of altered cells may represent a subpopulation capable of progressing to neoplasia, since hyperbasophilic areas and tumor cells exhibit similar enzyme deficiencies. (36 refs)

- 79-2575 Carcinogenic Azo Dyes--Detection of New Metabolites of 3'-Methyl-4-(methylamino)azobenzene in Rat Bile.** (Eng) Mori, Y. (Gifu Coll. Pharmacy, 5-6-1, Mitahora-higashi, Gifu 502, Japan); Horie, M.; Toyoshi, K. *Radioisotopes* 28(2): 72-77; 1979.

The metabolism of 3'-methyl-4-(methylamino)azobenzene (3'-Me-MAB) in rat bile was studied by an ion cluster technique. A mixture of unlabeled and labeled 3'-Me-MAB (10 mg in 1 ml cottonseed oil) was administered to male Wistar rats *po* via a stomach tube, and the bile was collected for 24 hr and hydrolyzed enzymically. During the 24-hr collection period, 28.7% of the administered dose was excreted into the bile. The hydrolyzed bile was chromatographed on an Amberlite XAD-2 column. The column was washed with water, and the metabolites were eluted with methanol and separated by thin-layer chromatography. The mass spectrum of each metabolite was measured and compared with those of authentic samples. Eight radioactive peaks were recognized in the chromatograms. The main metabolites were identified as follows: 3'-methyl-4-aminoazobenzene, 3'-methyl-4'-hydroxymethylaminoazobenzene, 3-acetaminotoluene, 3'-CHO-AB, 3'-CHO-MAB, 3'-COOH-AB, 3'-COOH-MAB, and 3'-CH₂OH-AB. The last three metabolites were oxidized at the ring methyl group and were detected for the first time as metabolites in bile. It is suggested that ring-methylated aminoazo dyes such as 3'-Me-MAB and 3'-methyl-4-dimethylaminoazobenzene may be bifunctional carcinogens. (10 refs)

- 79-2576 Analysis of 2-Acetylaminofluorene in Laboratory Animal Chow by Reverse Phase Liquid Chromatography.** (Eng) West, R. W. (Natl. Center Toxicological Res., Jefferson, AR, 72079); Oller, W. L. *J Liq Chromatogr* 1(2): 181-185; 1978.

A high-speed liquid chromatographic procedure for the analysis of 2-acetylaminofluorene (2-AAF) in laboratory animal chow is described. The extract is passed through alumina to remove coextracted compounds that would interfere with resolution of the 2-AAF peak on the analytical column. Background absorbance is reduced, and baseline resolution of 2-AAF is achieved. Reverse-phase liquid chromatography allows minimal clean-up of extracts with good column stability and high sample throughput. (2 refs)

- 79-2577 Enhancement of 2-Acetylaminofluorene Liver Carcinogenesis in Rats Fed a Choline-devoid Diet.** (Eng) Lombardi, B. (Dept. Pathology, Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA, 15261); Shinozuka, H. *Int J Cancer* 23(4): 565-570; 1979.

The effects of feeding a choline-deficient (CD) or a choline-supplemented (CS) diet on liver tumor induction by 2-acetylaminofluorene (AAF) were investigated in male Sprague-Dawley rats. The rats were fed a CD or a CS diet containing 0.0075% AAF. Three to eight animals were killed 1, 3, 4, and 6 mo thereafter. Well- to moderately well-differentiated hepatocellular carcinomas developed in 50% and 75% of rats fed the CD + AAF diet for 4 and 6 mo, respectively. Cholangiocarcinomas developed after 6 mo in 38% of the animals. No tumors developed in rats fed the CS + AAF diet. The results confirm those obtained previously with DL-ethionine and azaserine, showing that feeding a CD diet greatly potentiates the induction of liver tumors in rats by chemical carcinogens. (19 refs)

- 79-2578 Transformation of Cultured Mouse Mammary Glands by Aromatic Amines and Amides and Their Derivatives.** (Eng) Tonelli, Q. J. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA, 19111); Custer, R. P.; Sorof, S. *Cancer Res* 39(5): 1784-1792; 1979.

The transformation model of the cultured whole mammary gland of mice was applied to a study of the carcinogenic aryl amines and amides and their activated derivatives. Mouse mammary glands in whole organ culture, previously demonstrated by others to undergo lobuloalveolar development, functional differentiation, and glandular involution, are transformable by these compounds. The transformation, which involves an escape from the hormonal controls of these processes, results in the formation of nodulelike alveolar lesions that are morphologically similar to presumptive preneoplastic lesions (hyperplastic alveolar nodules) that occur in mice during viral and chemical mammary tumorigenesis. The

transformation system discriminates between carcinogens and noncarcinogens of analogous structures in the fluorenyl and naphthylenic chemical series, and it is sensitively responsive to the presence of the amino or amide group or their derivatives. In a series of fluorenyl carcinogens, N-2-fluorenylacetamide displayed very high transforming activity > N-hydroxy-N-2-fluorenylacetamide (high activity) > N-acetoxy-N-2-fluorenylacetamide (moderate activity) > 2-fluorenamine and 2-nitrofluorene (low activity). In contrast, the noncarcinogen fluorene had little if any activity. The two naphthylenic carcinogens, 1-naphthylamine and 2-naphthylamine, displayed moderate transforming activity, but the noncarcinogen naphthalene had no activity. Control glands treated only with the vehicle (dimethyl sulfoxide) were not transformed. Considerable structural changes at the cellular level were caused by the carcinogens, much less by the noncarcinogens, and essentially none by the vehicle. It remains to be determined whether the glands transformed by these carcinogens can progress to tumors in vivo. These and previous results with carcinogenic polycyclic aromatic hydrocarbons suggest that that mouse mammary gland in whole organ culture may be transformable by a broad spectrum of chemical carcinogens. (38 refs)

- 79-2579 A High Pressure Liquid Chromatography Procedure for the Separation of Metabolites of 2-Acetylaminofluorene from Cells in Culture.** (Eng) Raineri, R. (Chemical Carcinogenesis Program, NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Poiley, J. A.; Ernst, M. K.; Hillesund, T.; Pienta, R. J. *J Liquid Chromatography* 1(4): 457-467; 1978.

High-pressure liquid chromatography (HPLC) was used to determine picomole levels of the carcinogenic metabolite N-hydroxy-2-acetylaminofluorene (N-hydroxy-AAF) formed from N-2-acetylaminofluorene (AAF) by cells in culture. The extract from the cells and cell incubation medium was given a preliminary cleanup using thin-layer chromatography. N-hydroxy-AAF was then isolated using HPLC with a Waters Bondapak C₁₈/Corasil column and an acetonitrile-water elution system. Ring hydroxylation products were eluted with 23% acetonitrile, and AAF and the deacetylation product 2-aminofluorene (AF) were eluted with 33% acetonitrile. Resolution of N-hydroxy-AAF was accomplished using a linear gradient of 33%-99% acetonitrile. When cells in culture were incubated with 22 nanomoles/ml of AAF for 6 hr, 690 picomoles of N-hydroxy-AAF/10⁶ cells were formed by hamster hepatocytes compared with 13 and 8 picomoles/10⁶ cells for human embryo and hamster embryo cells, respectively. The rate of formation of N-hydroxy-AAF by hamster liver microsomes was 140 nanomoles/hr incubation/mg microsomal protein. (10 refs)

- 79-2580 Reactivity of the Antibodies to DNA Modified by the Carcinogen N-Acetoxy-N-acetyl-2-aminofluorene.** (Eng) Sage, E. (Centre de Biophysique

Moleculaire, C.N.R.S., 45045 Orleans Cedex, France); Fuchs, R. P.; Leng, M. *Biochemistry* 18(7): 1328-1332; 1979.

Rabbits were immunized with double-stranded native DNA (nDNA) that had been modified by in vitro reaction with N-acetoxy-N-acetyl-2-aminofluorene (AAAF), and the resulting antibodies were purified by affinity chromatography. This modified DNA is designated nDNA-AAF. The interactions between the purified antibodies or the Fab fragments and several ligands were studied. By radioimmunoassay, nDNA-AAF, heat-denatured DNA (dDNA)-AAF, and guanosine monophosphate (GMP)-AAF bound to the antibodies with about the same affinity. GMP modified by 2-aminofluorene (GMP-AF) interacted slightly less, and GMP modified by N-hydroxy-N-acetyl-2-aminofluorene (N-OH-AAF) did not interact with the antibodies. The values of the association constants deduced from fluorescence measurements for the binding of the Fab fragments to nDNA-AAF, dDNA-AAF, and GMP-AAF in 50 mM sodium chloride, pH 7.5, were of the same order of magnitude. The association constants for nDNA-AAF and dDNA-AAF and the amounts of precipitated antibodies decreased as the ionic strength increased. It is deduced that 1-1.5 phosphate groups interact by charge-charge interactions with the Fab fragments. The absorption and circular dichroism spectra of GMP-AAF, nDNA-AAF, and dDNA-AAF bound to the Fab fragments showed that the Fab fragments induced similar perturbation to the three ligands. These results indicate that the immunodeterminant group is the dGMP-AAF residue. (25 refs)

79-2581 Chronic Exposure to Low Concentrations of Halothane-Nitrous Oxide: Reproductive and Cytogenetic Effects in the Rat. (Eng) Coate, W. B. (Inhalation Toxicology Dept., Hazleton Labs. America, Inc., 9200 Leesburg Turnpike, Vienna, VA, 22180); Kapp, R. W.; Lewis, T. R. *Anesthesiology* 50(4): 310-318; 1979.

The reproductive, teratogenic, and mutagenic (cytogenetic) effects of low concentrations of halothane (HT) + nitrous oxide were determined in adult male and female Sprague-Dawley rats. The rats were exposed for 60 days prior to mating to 1 or 10 ppm HT + 50 or 500 ppm N₂O, respectively, for 7 hr/day, 5 days/wk. Inseminated females were exposed 7 hr/day from days 1 through 15 or from days 6 through 15 of their putative gestation. The former were allowed to deliver normally; fetuses of the latter were delivered by cesarean section on day 20. The males were exposed for an additional 40 wk (after the 3-wk mating period), after which bone marrow and spermatogonial cells were harvested for cytogenetic analysis. Exposure to 10 ppm HT + 500 ppm N₂O resulted in decreased ovulation and implantation efficiency and in slightly retarded fetal development (also seen at the lower level exposure). No major teratologic effect or unequivocal abortifacient effect of exposure of pregnant females during organogenesis or prior exposure of males was

observed. However, cytogenetic damage to both bone marrow and spermatogonial cells was found at both levels of exposure. (17 refs)

79-2582 Interstitial Cell Carcinomas of the Testis in BALB/c Male Mice Ingesting Methoxychlor. (Eng) Reuber, M. D. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501). *J Cancer Res Clin Oncol* 93(2): 173-179; 1979.

BALB/c and C3H male and female mice were fed 750 ppm methoxychlor [1,1'-(2,2,2-trichloroethylidene)bis(4-methoxy)benzene] or 100 ppm 1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane (DDT) in the diet for 2 yr. Interstitial cell carcinomas of the testis developed in 27/51 BALB/c male mice ingesting methoxychlor compared with 8/71 control mice. The testicular tumors were more malignant, developed at an earlier age, and were larger, less differentiated histologically, and more invasive in methoxychlor-treated mice than in control mice. They varied from well to poorly differentiated and undifferentiated and were capable of metastasis. They were also occasionally bilateral in treated mice. BALB/c mice receiving DDT and C3H male mice receiving methoxychlor or DDT did not develop testicular tumors. C3H male and female mice ingesting methoxychlor or DDT were more susceptible to the development of liver tumors than BALB/c mice. Methoxychlor-treated BALB/c mice also had lung tumors. The carcinogenicity of methoxychlor for the testis of BALB/c males is probably related to its estrogenic activity. (30 refs)

79-2583 Uptake of Benzo(a)pyrene, Carbaryl, DDT and Parathion in Cultured Human Cells: Re-evaluation. (Eng) Murakami, M. (Inst. Physical and Chemical Res., Wako-shi, Saitama 351, Japan); Fukami, J. *Bull Environ Contam Toxicol* 21(4/5): 478-482; 1979.

The uptake of the pesticides carbaryl, 1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane (DDT), and parathion and of benzo(a)pyrene (BP) by cultured human embryonic lung cells was investigated. Labeled chemicals were added to the culture medium at a concentration of 4×10^{-6} M. The medium was removed after 24 hr, and the cells were fractionated into acid-soluble, ethanol-soluble, and acid- and ethanol-insoluble fractions. DDT was easily removed from the cells by ethanol; a very small amount remained in the acid- and ethanol-insoluble fraction. The insoluble fraction contained 30 times as much carbaryl and 6x as much parathion as DDT. About 40% of the BP added to the medium was extracted with ethanol. In another experiment, the cells were incubated with the chemicals for 4 or 48 hr and ghost monolayers were prepared by detergent treatment (Triton X-100). The amount of chemicals associated with the ghost monolayers increased with duration of incubation. The association of DDT with the ghost monolayer was considera-

bly less than that of the other three chemicals. These results indicate that although a large amount of DDT is taken up by the cells, only a small fraction accumulates in the acid- and ethanol-insoluble fraction or the detergent-resistant cytoskeleton. DDT, therefore, associates mainly with surface membrane structures by a nonspecific absorption process. Carbaryl and parathion are taken up by the cells to a lesser degree than DDT, but they are more closely associated with cellular components such as proteins. (6 refs)

- 79-2584 Carcinogenic Risk Assessment: Ethylene Dibromide.** (Eng) Ramsey, J. C. (Toxicology Res. Lab., Health and Environmental Res., Dow Chemical Co., Midland, MI, 48640); Park, C. N.; Ott, M. G.; Gehring, P. J. *Toxicol Appl Pharmacol* 47(2): 411-414; 1979.

The incidence of cancer following ethylene dibromide (EDB) exposure predicted by a one-hit carcinogenesis model using parameters derived from a bioassay in rats was compared with that observed in a group of 156 workers employed in EDB production. The parameter estimates were derived from the age-specific incidence of tumor formation in male rats treated with 40 mg/kg/day EDB by gavage in corn oil. The one-hit model estimated that an almost 100% lifetime incidence of cancer should be expected in workers exposed for 40 yr to 0.4 ppm EDB at citrus fumigation centers. The duration of exposure to EDB at two locations (at 1 of which employees were also exposed to carbon tetrachloride and chloroform) was determined by work history records of each employee and by an industrial hygiene survey of airborne concentrations of EDB at one of the locations. Time-weighted av (TWA) concentrations of EDB were conservatively assumed to be 3.0 ppm (23 mg/m³). The effect of a different exposure concentration was also conducted at an assumed TWA of 0.9 ppm (6.9 mg/m³). The one-hit model predicted either 85 or 54 neoplasms above the normal background incidence at TWA EDB concentrations of 3.0 or 0.9 ppm, respectively, compared with the 8 neoplasms observed to date in both employee groups combined. It is concluded that the use of the one-hit model results in highly exaggerated risk estimates in humans. (8 refs)

- 79-2585 Whole-Body Autoradiography and Allied Tracer Techniques in Distribution and Elimination Studies of Some Organic Solvents.** (Eng) Bergman, K. (Dept. Toxicology, Univ. Uppsala, S-751 23 Uppsala, Sweden). *Scand J Work Environ Health* 5(suppl. 1): 263 pp.; 1979.

Whole-body autoradiography was used to study the distribution and elimination of ¹⁴C-labeled benzene, toluene, xylene, styrene, methylene chloride, chloroform, carbon tetrachloride, and trichloroethylene in mice following inhalation exposure. All solvents were rapidly taken up by fatty and nervous tissues, where they were retained for various periods of time

depending largely on their fat solubility. Unexpectedly long retention times were noted for the chlorinated solvents, particularly chloroform, which was retained in the cerebellum, meninges, and spinal nerves. Metabolites appeared rapidly in several organs, primarily the liver and kidney, and they were excreted in the urine and bile. Toluene and xylene metabolites were completely extractable, whereas firmly bound metabolites of benzene, styrene, and the chlorinated solvents were found in the liver, kidney, and bronchi. Three-compartment pharmacokinetics were observed for most of the solvents studied, although a two-compartment model fit the elimination rate curves for styrene, methylene chloride, and chloroform in the exhaled air. The fat solubilities of the solvents influenced their pharmacokinetics, lower rate constants generally being obtained for the expiration of the more fat-soluble compounds. (478 refs)

- 79-2586 Reactions of Trichloroethylene Epoxide in Aqueous Systems.** (Eng) Henschler, D. (Inst. Toxicology, Univ. Wurzburg, Versbacher Strasse 9, D-8700 Wurzburg, W. Germany); Hoos, W. R.; Fetz, H.; Dallmeier, N.; Metzler, M. *Biochem Pharmacol* 28(4): 543-548; 1979.

The reactivity of trichloroethylene epoxide (TE) in aqueous systems was studied in an effort to determine its role in the metabolism, mutagenicity, and carcinogenicity of trichloroethylene (T). TE decomposed completely in unbuffered water into several acid products. Under C-C fission, it decomposed to carbon monoxide and formate. Glyoxylic acid and dichloroacetic acid were also formed. These results are contrary to those obtained in vivo, where T is metabolically transformed exclusively to trichlorinated C₂-compounds. It is suggested that T is epoxidized by mixed function oxygenases and that TE rearranges immediately within the hydrophobic premise of the enzyme, due to the catalytic action of the trivalent iron of P-450, to the nonreactive chloral. Thus, under normal in vivo conditions, the highly reactive epoxide is protected from the decomposition reactions observed in vitro. This hypothesis is consistent with the very low mutagenic and doubtful carcinogenic potential of T. (23 refs)

- 79-2587 Evidence for Possible Lack of Safety for Human Consumption of Dichloroacetate, a "Sister Compound" and Frequent Ingredient of the Non-Vitamin "B₁₅" (Pangamate) (Meeting Abstract).** (Eng) Herbert, V. (Bronx Veterans Admin. Hosp., New York, NY); Gardner, A.; Colman, N. *Am J Clin Nutr* 32(4): 952; 1979. (3 refs)

- 79-2588 Mutagenic and Alkylating Metabolites of Halo-Ethylenes, Chlorobutadienes and Dichlorobutenes Produced by Rodent or Human Liver Tissues. Evidence for Oxirane Formation by P450-linked Microso-**

mal Mono-oxygenases. (Eng) Bartsch, H. (International Agency for Res. Cancer, 150 Cours Albert-Thomas, F-69372 Lyon, Cedex 2, France); Malaveille, C.; Barbin, A.; Planche, G. *Arch Toxicol* 41(4): 249-277; 1979.

The abilities of various haloolefins to induce *his+* revertants in *Salmonella typhimurium* strains TA100 and TA1530 in the presence of mouse or human postmitochondrial liver supernatants were studied. With mouse liver microsomes, mutagenicity decreased in the following order: 3,4-dichlorobutene-1 > 1-chlorobutadiene > 2-chlorobutadiene > vinyl bromide > vinylidene chloride (VDC) > vinyl chloride (VC). 1,1,2-Trichloroethylene and 1,1-difluoroethylene were marginally mutagenic, and tetrachloroethylene and vinyl acetate were nonmutagenic. With human liver fractions, VC, vinyl bromide, VDC, and 2-chlorobutadiene were mutagenic. 1,4-Dichloro-2,3-epoxybutane was less mutagenic than 1,4-dichlorobutene-2, the mutagenicity of which was increased by liver microsomes. The mutagenicities of VC and VDC were increased up to twofold in the presence of liver microsomes from rats pretreated with phenobarbital or 3-methylcholanthrene, but pregnenolone-16 α -carbonitrile, aminoacetonitrile, and disulfiram pretreatment decreased the mutagenic effects. VC and, probably, vinyl bromide were epoxidized by mouse liver microsomes. 2-Chlorobutadiene, but not 1,1-difluoroethylene, 1,1-dichloroethylene, or 1,1,2-trichloroethylene, yielded an alkylating intermediate. The alkylating activity of 2-chloro- and 1-chlorobutadiene, 3,4-dichlorobutene-1, and 1,4-dichlorobutene-2 and its 2,3-epoxide derivative was not related quantitatively to mutagenicity. The data indicate that oxidation of the double bond in certain haloolefins is a common pathway in the formation of biologically active intermediates. (78 refs)

79-2589 Y-Chromosomal Nondisjunction in Dibromochloropropane-exposed Workmen. (Eng) Kapp, R. W. (Genetic Toxicology, Hazleton Lab. America, Inc., Vienna, VA, 22180); Picciano, D. J.; Jacobson, C. B. *Mutat Res* 64(1): 47-51; 1979.

The incidence of Y-chromosome nondisjunction (YFF) in the sperm of 18 workers exposed to 1,2-dibromo-3-chloropropane (DBCP) from 6 to 18 mo (mean, 15.2 mo) was investigated. In semen samples from 15 individuals with no known exposure to DBCP, an av of 41.5% (36.7%-46.3%) of the spermatozoa were positive for Y chromosomes (YF bodies), and the av YFF frequency was 1.2% (0.8%-1.8%). Samples from the DBCP-exposed workers showed an av YF frequency of 41.8% (36.3%-46.3%) and an av YFF of 3.8% (2.0-5.3%). The differences in YF frequency between the exposed and nonexposed groups were not significant, whereas the differences in YFF frequency were very highly significant. (15 refs)

79-2590 A Teratogenicity and Tissue Distribution Study on Dibromochloropropane in the Rat. (Eng)

Ruddick, J. A. (Food Directorate, Health Protection Branch, New Res. Center, Tunney's Pasture, Ottawa, Ontario K1A 0L2, Canada); Newsome, W. H. *Bull Environ Contam Toxicol* 21(4/5): 483-487; 1979.

The teratogenicity and tissue distribution of dibromochloropropane (DBCP) was studied in primiparous Wistar rats. Groups of rats received 0, 12.5, 25.0, or 50.0 mg/kg DBCP po on gestation days 6-15. Necropsies were performed on day 22. Another group of pregnant females was treated with 25 mg/kg DBCP po on gestation days 6-15 and sacrificed at 1, 3, 6, 12, or 24 hr after the last DBCP dose; the fetuses were assayed for DBCP. DBCP was not teratogenic at the doses given, but it was toxic to both the dams and fetuses. There was a significant difference between the wt of fetuses from the 50.0-mg/kg-dosed dams and that of control fetuses. This fetotoxic effect is related to the maternal toxicity of DBCP. Heart, brain, fat, and blood contained detectable amounts of DBCP at 12 hr after administration, but by 24 hr only fat still contained DBCP (0.17 ppm). Apparently, there was no accumulation of DBCP in the tissues examined (spleen, brain, heart, lung, kidney, liver, and blood), except fat. (5 refs)

79-2591 The Effect of Chloroform Ingestion on Some Hepatic Carcinogen Metabolising Enzymes in Rats. (Eng) Capel, I. D. (Res. Dept., Marie Curie Foundation, The Chart, Oxted, Surrey RH8 0TL, England); Williams, D. C. *IRCS Med Sci (Cancer)* 7(2): 82; 1979.

The ingestion of chloroform at 0.15 mg/kg/day for 14 days did not adversely affect gross liver wt or microsomal protein content in male Sprague-Dawley rats. However, the ingestion of chloroform at 0.15 or 15 mg/kg/day increased benzo(a)pyrene binding by DNA in the presence of 1,1,1-trichloropropene-2,3-oxide, suggesting that epoxide hydratase activity was increased. (6 refs)

79-2592 Radiographic Study of Gastric Hyperplasia Induced by Polychlorinated Biphenyls in the Rhesus Monkey. (Eng) Silverman, S. (Dept. Veterinary Radiology, Univ. California, Davis, 4301 X Street, Davis, CA, 95817); Rosenquist, C. J.; McNulty, W. P. *Invest Radiol* 14(1): 65-69; 1979.

The effect of 3,4,3',4'-tetrachlorobiphenyl (TCB: 3 ppm in the diet) on three immature male rhesus monkeys was studied radiographically. Clinical signs of toxicity, including swelling and erythema of the eyelids and periorbital edema, developed in 14-17 days. By day 23, two animals showed vomiting, anorexia, and wt loss; the third had no gastric distress. Radiographic examination of the first two monkeys revealed thickening of the gastric wall along the greater curvature of the distal body and antrum and narrowing and rigidity of the junction of the body and antrum. By day 62, the lesion in-

volved a larger area, thickening was increased, and nodularity and irregularity of the mucosal and serosal surfaces were observed. Both of these animals died within 62 days. The third TCB-treated monkey showed no more than a possible lesion on radiographic examination, and there was no evidence of further gastric involvement on subsequent examinations. Radiographically, polychlorinated biphenyl-induced lesions in the rhesus monkey strongly resemble an infiltrating-type carcinoma and therefore provide an excellent model for evaluating radiographic diagnoses of early infiltrative-type lesions. (6 refs)

- 79-2593 Changes in Peroxisomes in Preneoplastic Liver and Hepatoma of Mice Induced by α -Benzene Hexachloride.** (Eng) Tsukada, H. (Dept. Pathology, Cancer Res. Inst., Sapporo Medical Coll., S-1, W-17, Chuo-ku, Sapporo 060, Japan); Gotoh, M.; Mochizuki, Y.; Furukawa, K. *Cancer Res* 39(5): 1628-1634; 1979.

Changes in the number and size of peroxisomes (POS's) in hepatomas and hyperplastic nodules (HPN's) induced in the male DD mouse liver by α -benzene hexachloride (BHC) were determined histochemically and electron microscopically. The mice were divided into two groups: one was fed a diet containing 500 ppm BHC and the other was fed the BHC diet plus, 4 wk before sacrifice, 1% ethyl- α -p-chlorophenoxyisobutyrate (CPIB). CPIB is a well-known POS inducer. Six mice from each group were examined 16-36 wk after the start of the BHC diet. HPN were found in 1/6 mice at 16 wk and 5/6 mice at 20 wk, irrespective of CPIB treatment. At 24 and 28 wk, HPN were found in 5/6 mice and hepatomas in 2/6 mice of both groups. At 32 and 36 wk, all mice had HPN, and 3/6 mice in each group had hepatomas. Although most of the hepatomas were well-differentiated and contained a considerable number of POS's they showed no response to the POS-inducing stimulus of CPIB. However, the size of these organelles was increased; ie, the induction of peroxisomal protein synthesis may not be lost completely, in contrast to the induction of POS proliferation. In agreement with previous findings, hepatocytic hyperplasia of the hepatocytes was found to originate within the centrilobular zone of the liver. As a result of this proliferation, HPN eventually formed. Within the nodules, hepatocytic proliferation and "maturation" occurred simultaneously. Maturation was characterized by an increase in the number of POS's and in the inducibility of these organelles by CPIB. Cells within the HPN that did not show further maturation or lost their POS inducibility during maturation continued to proliferate, resulting in hepatoma formation. These results are similar to those of rat hepatocarcinogenesis studies, except that abnormal matrical tubules of POS's were not formed in the mouse HPN cells in response to CPIB. (28 refs)

- 79-2594 Effect of Acrylonitrile on Primary Syrian Golden Hamster Embryo Cells in Culture: Transformation and DNA Fragmentation.** (Eng) Parent, R. A. (Food

and Drug Res. Labs., P.O. Box 107, Route 17C, Waverly, NY, 14892); Casto, B. C. *J Natl Cancer Inst* 62(4): 1025-1029; 1979.

The effect of acrylonitrile (ACN) on the transformation of primary Syrian golden hamster embryo cells (HEC) in culture was established by two approaches. The focus assay involved the plating of small numbers of HEC in tertiary culture and counting the chemically transformed foci. The second assay involved the enhancement of viral transformation performed by inoculating the HEC with an oncogenic adenovirus after ACN treatment and counting the resulting virus-transformed foci 3 wk later. Application of 50 or 100 μ g/ml ACN produced foci of morphologically transformed cells. When similar cells were pretreated with simian adenovirus (SA7) and subsequently treated with ACN (25-200 μ g/ml), up to an 8.9-fold increase in the frequency of virus-transformed foci was noted over that found in cultures treated only with SA7. When [3 H]thymidine-labeled primary Syrian golden HEC were treated with ACN and cellular DNA was subsequently subjected to alkaline sucrose gradients, a shift in the sedimentation pattern reminiscent of that observed for chemical carcinogens was noted. These observations support recent studies indicating that ACN may be carcinogenic. (23 refs)

- 79-2595 Sensitivity of Hexokinase and Glucokinase to Exposure to Hormones During Hepatocarcinogenesis.** (Rus) Kil'dema, L. A. (Inst. Experimental and Clinical Medicine, Tallin, USSR). *Vopr Med Khim* 24(1): 36-41; 1979.

The effect of hydrocortisone (HC) and insulin (IS) on the activity of key carbohydrate metabolism enzymes during diethylnitrosamine (DENA)-induced hepatocarcinogenesis was evaluated in Wistar rats. The rats received 2.5 mg/kg/day DENA in the drinking water, 6 days/wk, for 8 mo. The hormones were given at the end of the 3rd, 5th, 6th, 7th or 8th mo (HC: 5 mg/kg/day, for 7 days, im; IS: 2 IU/100 g, bid, for 2 days sc). Animals were sacrificed after hormone administration, and the activity and isoenzyme spectrum of hexokinase (HK) and glucokinase (GK) in the liver were assessed. Administration of HC to control rats caused a 25% decrease in HK activity (primarily due to a decrease in the activity of isozyme II) and a 23%-38% decrease in GK activity. IS did not affect HK activity, but it increased the activity of GK by 177%. The first precancerous changes (focal hyperplasia) were detected after 5 mo of DENA treatment: after 6-7 mo, the rats had 3- to 4-mm-diameter tumor nodules and hepatomas, and after 8 mo, they developed highly differentiated hepatocarcinomas. The effect of HC on HK and GK activities was less pronounced in rats with DENA-induced hepatomas than in controls: there was a 17% and 12% decrease in HK and GK activity, respectively, after 5 mo of DENA treatment and a 8% and 12% decrease after 8 mo. IS did not affect HK activity, but it increased GK activity by 189% after 5 mo, and by 188% after 8 mo. (21 refs)

- 79-2596 Study of Mutagenicity of Nitroso Compounds in *Escherichia coli*.** (Rus) Pogodina, O. N. (Inst. Cytology, Leningrad, USSR). *Genetika* 14(12): 2113-2118; 1978.

The mutagenic activity of two carcinogenic nitrosamines was studied in two strains of *Escherichia coli*. Incubation of the *HfrH thi-* and *his-* strains with 5% dimethylnitrosamine (DMNA) and 1% diethylnitrosamine (DENA) for 1 hr decreased the survival of the treated cells. The *thi-* strain was slightly more sensitive (62.0% and 58.7% of the cells survived treatment with DMNA and DENA, respectively, compared with 66.0% and 68.8% for *his-* strain). Both carcinogens lacked mutagenic activity. However, in vitro hydroxylation of the compounds with 0.1 M sodium nitrite resulted in a 1.5-fold increase in the mutagenic activity of DMNA and 3.5-fold increase in the mutagenic activity of DENA. Both forward and backward mutations were induced. (22 refs)

- 79-2597 Antigenic and Morphological Differences in Diethylnitrosamine-induced Hepatomas as a Function of Dose.** (Spa) Uribarrena, R. (Departamento de Investigaciones Medicas, Universidad de Navarra, Pamplona, Spain); Perez Miranda, M.; Pons, F.; Cabarcos, A.; Ayensa, C.; Amezcaga, A. *Rev Esp Oncol* 25(2): 221-240; 1978.

The morphology and antigenic characteristics of hepatomas induced by diethylnitrosamine (DENA) were studied in Wistar rats as a function of dose. The total dose administered in drinking water was 8 mg/kg/day in Group A and 4 mg/kg/day in Group B (30 rats each). The high dose produced cirrhotic lesions and then hepatomas after 22 wk, but hepatomas without preceding or concurrent cirrhosis were found in Group B. In this group, the first tumor appeared after 30 wk. The malignant liver tissue was characterized by a high albumin level and the exclusive presence of β -transferin, which is not found in cirrhotic or normal livers. Circulating neoantigen was found exclusively in the tumor-bearing animals; it was present in 18/35 sera. The antigenic spectrum of the Group A rats was more complex than that of the Group B rats, in whom the max number of bands was 3. The increased antigenic complexity found in Group A was probably due to the toxic effects of DENA, which produced morphological and protein changes that had nothing to do with the neoplastic character of the cell. (25 refs)

- 79-2598 Volatile Nitrosamine Contamination of Laboratory Animal Diets (Letter to Editor).** (Eng) Edwards, G. S. (Thermo Electron Corp., Waltham, MA, 02154); Fox, J. G.; Policastro, P.; Goff, U.; Wolf, M. H.; Fine, D. H. *Cancer Res* 39(5): 1857-1858; 1979.

The presence of N-nitroso contaminants in a small sampling

of laboratory animal diets is reported. Low levels of the carcinogen N-nitrosodimethylamine (NDMA: 1-4 ppb) were found in 11/12 samples of commercial pelleted diets for laboratory animals. Higher levels (5-50 ppb) of NDMA were found in 3/7 samples of the NIH open-formula rat and mouse ration. The fish meal used in this diet contained NDMA in quantities sufficient to account for most of the contamination. In addition, several samples of the NIH diet contained low levels of N-nitrosopyrrolidine (0-2.1 ppb). The implications of these findings with respect to carcinogenicity testing are summarized briefly. For example, nitrosamine dietary contaminants could act synergistically with other (test) carcinogens or cocarcinogens to increase tumor incidence or alter the target organ. (13 refs)

- 79-2599 Increased Excision of O⁶-Methylguanine from Rat Liver DNA after Chronic Administration of Dimethylnitrosamine.** (Eng) Montesano, R. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 2, France); Bresil, H.; Margison, G. P. *Cancer Res* 39(5): 1798-1802; 1979.

The effect of chronic exposure of male BDIV rats to dimethylnitrosamine (DMN) on the ability of the liver to excise O⁶-methylguanine (OMG) from DNA in vivo was examined. The rats were given DMN (2 mg/kg/day, 5 days/wk) by stomach tube for a total of 9 wk, the final dose being of ¹⁴C-labeled material. Control rats received only the labeled DMN. Liver DNA was isolated 2-12 hr later, and normal and alkylated purines were determined after hydrolysis in mild acid chromatography on Sephadex G-10. The levels (measured as disintegrations per minute/micromole of parent base) of 7-methylguanine in the DNA of the experimental rats were the same as or slightly higher than those of the control animals, and the persistence of this product was similar in both groups. This was also true for 3-methyladenine. In contrast, the initial amount of OMG in the liver DNA of the experimental rats was one-third of the amount found in the control rats, and the rate of loss of this product from DNA was higher in the experimental animals. These differences were reflected in the alkylation product ratios: the 3-methyladenine:7-methylguanine ratios were closely similar in the two groups of animals at all times, whereas the OMG:7-methylguanine ratio was initially three times higher in the control animals and fell more slowly. DNA synthesis (as measured by the incorporation of [³H]thymidine) was higher in the liver, kidney, and lung of the experimental rats. (43 refs)

- 79-2600 Kupffer Cell Sarcoma in Rats after Exposure to Small Doses of Dimethylnitrosamine and N-2-Acetylaminofluorene During Hepatic Regeneration.** (Eng) Chopra, P. (Dept. Pathology, All India Inst. Medical Sciences, New Delhi 110016, India); Manga, A.; Nayak, N. C. *J Natl Cancer Inst* 62(4): 1089-1095; 1979.

CHEMICAL CARCINOGENESIS

The occurrence of primary liver sarcomas in normal, CCl₄-treated, or 70% hepatectomized (He-x) adult male Wistar rats treated with dimethylnitrosamine (DMN: 0.8 mg/100 g, once or twice at an interval of 14 days) or N-2-acetylaminofluorene (AAF: 2 mg/100 g/day for 3 days) is reported. Sarcomas occurred in 3.8% of rats treated with CCl₄ (100 µl/100 g) + DMN, 7.8% of rats treated with He-x + DMN, 9.2% of rats treated with He-x + AAF, 5.3% of normal animals treated with DMN, and 0% of normal animals treated with AAF. The differences in incidence between groups were not particularly significant. The sarcomas showed a consistent pattern in almost all animals. The tumor cells contained evidence of phagocytosis and many structural features attributed to Kupffer's cells. They grew along the sinusoids or filled these spaces, and sometimes they invaded the hepatic vein tributaries. Thus, it appeared that the sarcomas originated from Kupffer cells. In 7/13 rats in which the lungs were examined, multiple tumor emboli resembling those in the liver were present in the blood vessels. Reticuloendothelial cell hyperplasia was observed in the spleen, and a tumor identical to those in the liver was observed in one rat. This animal also had an intestinal tumor that resembled those in the liver and spleen. (24 refs)

- 79-2601 Persistence of Methylated Bases in Ribonucleic Acid of Syrian Golden Hamster Liver after Administration of Dimethylnitrosamine.** (Eng) Margison, G. P. (Paterson Labs., Christie Hosp., Manchester M20 9BX, England); Margison, J. M.; Montesano, R. *Biochem J* 177(3): 967-973; 1979.

Syrian golden hamster liver ribosomal RNA was isolated up to 96 hr after the hamsters were injected ip with ¹⁴C-dimethylnitrosamine (DMN: 25 or 2.5 mg/kg). 7-Methylguanine, 3-methylcytosine, O⁶-methylguanosine and 1-methyladenosine concentrations were measured after acidic or enzymic hydrolysis of the RNA to bases or mononucleosides followed by ion-exchange chromatography. After the high dose, alkylation appeared to be max at 12 hr, followed by a decrease, which was most rapid between 24 and 48 hr. After the low dose, the amounts of alkylation products were seven times lower, and no changes in the rates of loss of the products were observed between 7 and 96 hr. After both the high and low dose, the relative amounts of the four alkylation products appeared not to change between 7 and 96 hr, posttreatment. These results suggest that base-specific excision repair does not exist for RNA alkylation products in this system. (32 refs)

- 79-2602 Mediated Mutagenesis of Dimethylnitrosamine in *Neurospora crassa* by Various Metabolic Activation Systems.** (Eng) Whong, W. Z. (Cancer Res. Center, Thermo Electron Corp., Waltham, MA); Ong, T. *Cancer Res* 39(5): 1525-1528; 1979.

Studies were conducted to determine whether dimethylni-

trosamine (DMN) can be converted to metabolites mutagenic to *Neurospora crassa* in different in vivo and in vitro activation systems. The activation of DMN to mutagenic metabolites by liver, lung, and kidney of male Sprague-Dawley rats and male Swiss outbred albino mice was also compared in the in vivo and in vitro assays. Four metabolic activation systems (growth-mediated, mycelium extract-mediated, host-mediated, and organ homogenate-mediated) were used to study the mutagenicity of DMN in both forward and reverse mutation systems in the *ad-3* (adenine-3) region of *N. crassa*. DMN was not mutagenic in *Neurospora* if conidia alone were treated. It was highly mutagenic, however, if conidia were treated with this compound under any of the four activation systems. Quantitative differences in DMN-induced mutation frequencies were observed between in vivo (growth- and host-mediated) and in vitro (mycelium extract- and organ homogenate-mediated) activations. The efficiency of the conversion of DMN to mutagenic metabolites by the rodent organs appeared to be in a reversed order between the host-mediated (liver > kidney > lung) and the organ homogenate-mediated (lung > kidney > liver) assays. Inductions of reverse mutations in strain N23 indicated that DMN induces base-pair substitutions in *N. crassa*. (23 refs)

- 79-2603 Persistence of DNA Damage During Development of Liver Angiosarcoma in Rats Fed Dimethylnitrosamine.** (Eng) Abanobi, S. E. (Dept. Pathology, Univ. Toronto, Medical Sciences Building, Toronto, Ontario M5S 1A8, Canada); Farber, E.; Sarma, D. S. *Cancer Res* 39(5): 1592-1596; 1979.

Liver DNA damage induced by dimethylnitrosamine (DMN) and the subsequent repair of this damage under conditions that lead to the development of cancer were studied. Chronic feeding of a diet containing 50 ppm DMN to male Wistar rats resulted in liver DNA damage monitored as slow sedimentation of the DNA, compared with that of control liver DNA, in alkaline sucrose gradients. The damage in rat liver DNA could be seen within 2 days after DMN treatment, and it was progressive with duration of feeding up to 8 wk. Extended feeding up to 15-31 wk did not result in a proportionate increase in DNA damage. The DNA damage observed at 8 wk persisted until 31 wk, at which time liver angiosarcoma was present. Despite the fact that the DNA damage induced by DMN appears to involve the bulk of the liver DNA, the tumors developed were entirely from vascular endothelium. (25 refs)

- 79-2604 Evidence for Several Demethylase Enzymes in the Oxidation of Dimethylnitrosamine and Phenylmethylnitrosamine by Rat Liver Fractions.** (Eng) Kroege-Koepeke, M. B. (Frederick Cancer Res. Center, P.O. Box B, Frederick, MD, 21501); Michejda, C. J. *Cancer Res* 39(5): 1587-1591; 1979.

An attempt was made to provide additional evidence for the

existence of a number of nitrosamine demethylases, some of which are membrane-bound and others which are apparently soluble and probably perform their function in the cytoplasm. The steady-state kinetics and isotope effects were examined for the demethylation of dimethylnitrosamine (DMN) and phenylnitrosamine (PMN), as well as their deuterated analogs, using the S-9 supernatant fraction, the microsomal pellet, and the postmicrosomal supernatant from rat livers. The isotope effect (ratio of max rates for the deuterated and light substrates) using the S-9 fraction from Long-Evans rat livers was 1.82 for DMN and 5.38 for PMN. Phenobarbital induced dimethylnitrosamine demethylase activity in the microsomal pellet of both Long-Evans and Sprague-Dawley rats, but it repressed this activity in the postmicrosomal supernatant from Long-Evans rats and increased it markedly in the postmicrosomal supernatant from Sprague-Dawley rats. There was nitrosamine demethylase activity in the so-called "pH 5 enzymes" and in the supernatant from that preparation. The latter activity showed substantially different characteristics from those found in the other fractions. (12 refs)

79-2605 Chromatographic Determination of Volatile N-Nitrosamines in Natural and Waste Waters.

(Rus) Kosmenko, L. D. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Kosmenko, V. G. *Gig Sanit* (2): 53-57; 1979.

The efficacy of various chromatographic techniques for the detection of volatile nitrosamines in bodies of water and wastewater was tested. Four dialkyl nitrosamines, dimethylnitrosamine (DMNA), diethylnitrosamine (DENA), di-n-propylnitrosamine (DPNA), and di-n-butylnitrosamine (DBNA), were analyzed in water samples from the Neva River at Leningrad and in wastewater samples from a hydrolysis plant. The most reliable results were obtained with the simultaneous use of gas-liquid or liquid chromatography and spectrophotometry. The Neva River water contained < 5 µg/ml DMNA, DENA, DPNA, or DBNA, the wastewater < 20 µg/ml. (15 refs)

79-2606 Vascular Liver Tumors Induced in *Mastomys (Praomys) natalensis* by Single or Twofold Administration of Dimethylnitrosamine. (Eng) Wayss, K. (Inst. Experimental Pathology, German Cancer Res. Center, Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Banasch, P.; Mattern, J.; Volm, M. *J Natl Cancer Inst* 62(5): 1199-1207; 1979.

A study was made of the morphology and morphogenesis of vascular liver tumors induced in the multimammate mouse *Mastomys (Praomys) natalensis* by dimethylnitrosamine (DMNA: single dose of 10 mg/kg or 2 doses of 5 mg/kg, ip). Benign hemangioendotheliomas (HET's) developed in 164/173 rodents, malignant HET's in 10/173. There were no

differences associated with number of injections or interval between injections (1-7 days), but males reacted to the carcinogen somewhat earlier and more strongly than females. The first histologic alterations were focal dilatations of the sinusoids. The benign HET's that subsequently developed were characterized by solitary or multiple distended blood lacunae, and they resembled peliosis hepatis macroscopically. The lacunae were frequently thrombosed. The coating endothelium appeared only slightly altered. In advanced stages, entire liver lobes could be affected in the form of a diffuse hemangioendotheliomatosis, and in some animals the histologic picture largely corresponded to that of cavernous hemangioma in humans. Rupture of the HET's often gave rise to hemorrhaging into the abdominal cavity. Unequivocal hemangiosarcomas were found in 10 animals. In more advanced stages, the tumor cells displaced the liver parenchyma, and metastases were observed to the lung in one animal and to the adrenal cortex in another. It is possible that sinus dilatations, benign HET's, and hemangiosarcomas are only different stages of a uniform pathogenetic series. (52 refs)

79-2607 Induction of 6-Thioguanine Resistance in Chinese Hamster Lung Cells Treated with Dimethylnitrosamine, 2-Aminoanthracene or 7,12-Dimethylbenz(a)anthracene in the Presence of Rat Liver Microsomes. (Eng) Huang, S. L. (Northrop Services, Inc., Environmental Sciences Group, P.O. Box 12313, Research Triangle Park, NC, 27709); Whong, W. Z. *Toxicol Lett* 3(4): 209-214; 1979.

The mutagenicity of dimethylnitrosamine [DMN (5-100 mM)], 2-aminoanthracene [AA (25-200 µg/ml)], and 7,12-dimethylbenz(a)anthracene [DMBA (25-200 µg/ml)] was studied at the hypoxanthine guanine phosphoribosyl transferase (HGPRT) locus in Chinese hamster lung cells. These compounds induced 6-thioguanine resistance in the presence of rat liver microsomes, but not in their absence. The frequencies of mutations induced by these compounds were dose-dependent. 79-2608 The Percutaneous Absorption of N-Nitrosodietanolamine Through Excised Human Skin (Meeting Abstract). (Eng) Bronaugh, R. L. (Div. Toxicology, Food and Drug Admin., Washington, DC); Congdon, E. R.; Scheuplein, R. J. *J Invest Dermatol* 72(4): 204; 1979. (no refs)

79-2609 The Percutaneous Absorption of N-Nitrosodietanolamine Through Excised Human Skin (Meeting Abstract). (Eng) Bronaugh, R. L. (Div. Toxicology, Food and Drug Admin., Washington, DC); Congdon, E. R.; Scheuplein, R. J. *Clin Res* 27(2): 522A; 1979. (no refs)

79-2610 Dedifferentiation of Liver and Pancreas Induced by Chemical Carcinogens (Meeting Abstract). (Eng) Bockman, D. E. (Dept. Anatomy, Medical Coll. Georgia, Augusta, GA); Black, O.; Webster, P. D. *Gastroenterology* 76(5, part 2): 1104; 1979. (no refs)

79-2611 Carcinogenic Effects of Di(2-hydroxypropyl)nitrosamine (DHPN) in Male Wistar Rats: Promotion of Pancreatic Cancer by a Raw Soya Flour Diet. (Eng) Levison, D. A. (Dept. Pathology, Univ. Dundee, Dundee, Scotland); Morgan, R. G.; Brimacombe, J. S.; Hopwood, D.; Coghill, G.; Wormsley, K. G. *Scand J Gastroenterol* 14(2): 217-224; 1979.

The effect of raw soya flour (RSF) on the carcinogenicity of di(2-hydroxypropyl)nitrosamine (DHPN, 0.2 mg/wk ip for 4 wk and then 0.1 mg/wk for 20 wk) in the pancreas was studied in four groups of male Wistar rats (16 rats/group). DHPN-treated and untreated rats were given a diet of RSF or heated (control) soya flour (HSF). Pancreatic wts were significantly increased in rats fed RSF compared with those of rats fed HSF; DHPN significantly reduced this hypertrophy. Zymogen-containing nodules with large pleomorphic nuclei and many mitotic figures were observed in the pancreases of rats given RSF, RSF + DHPN, and, to a lesser extent, HSF + DHPN. Among the other tumors found in rats given RSF + DHPN or HSF + DHPN were invasive squamous cell carcinomas of the esophagus (4 and 4, respectively), intestinal adenocarcinomas (2 and 4), hepatic lesions (3 and 4) and lung cancers (5 and 2). It is possible that dietary factors that result in the excessive and sustained release of cholecystokinin may sensitize the pancreas to environmental carcinogens. The number of rats with microscopic hyperplastic pancreatic nodules were 4/16, 15/16, 6/16, and 13/13 (only 13 were suitable for morphological study) in the HSF, RSF, HSF + DHPN, and RSF + DHPN groups, respectively. The corresponding figures for mean number of nodules/section of pancreas were <1, 4, <1, and 8; for mean area occupied by nodules/section of pancreas <2%, 10%, <2%, and 25%; and for number of rats with pancreatic carcinoma, 0/16, 0/16, 0/16, and 2/16 (these tumors were mucin-producing invasive adenocarcinomas). Ten pancreases in the RSF + DHPN group showed macroscopic nodules after 9 mo; two contained, in addition, adenomatous acinar cell nodules, and one contained an adenoma apparently arising from ductal epithelium. (19 refs)

79-2612 Intestinal Tumors Induced by a Single Intraperitoneal Injection of Methyl(acetoxymethyl)nitrosamine in Three Strains of Rats. (Eng) Berman, J. J. (Lab. Experimental Pathology, NCI, Bethesda, MD, 20014); Rice, J. M.; Wenk, M. L.; Roller, P. P. *Cancer Res* 39(5): 1462-1466; 1979.

To determine whether the strain of rat determines the quantity or type of intestinal tumors induced by methyl(acetoxymethyl)nitrosamine (DMN-OAc), 5-wk-old male and female rats of the Sprague-Dawley (SD), Buffalo (BUF), and Fischer (F344) strains were given a single ip injection of DMN-OAc. The dose used, 13 mg (0.1 micromole)/kg, was one-half of the acute ip median lethal dose determined for 5-wk-old male SD rats. In each strain treated with DMN-OAc, a large number of intestinal epithelial tumors developed. The histological features of these tumors were the same in all strains and both sexes. In each strain, females had fewer induced tumors of the small intestine (SI) and large intestine (LI) than males of the same strain. The greatest difference between males and females in the frequency of SI tumors induced was observed in F344 rats. These were 1.7 SI tumors/male F344 rat and only 0.2 SI tumor/female F344 rat. The lowest induced tumor incidence was seen in BUF rats (0.3 SI tumor/male rat and 0.2 SI tumor/female rat). In SD rats, there were 2.0 SI tumors/male and 1.3 SI tumors/female. In all strains and both sexes, many more SI tumors were induced than LI tumors. Tumors occurred throughout the SI and colon and in the cecum, and they tended to occur most frequently in the distal ileum. Localization was the same in all strains and sexes studied. Other tumors induced with high frequency by ip administration of DMN-OAc were schwannomas (primary in peritoneum), testicular mesotheliomas, and splenic angiosarcomas. (13 refs)

79-2613 Cumulative Catalytic Effects of Some Physiologically Active Ions on the Rate of Nitrosation of N-Methylaniline In Vitro. (Eng) Lathia, D. (Dept. Nutrition Physiology, Fachhochschule Niederrhein, Richard-Wagnerstrasse 101, 405 Monchengladbach, W. Germany); Rutten, M. *Nutr and Cancer* 1(2): 19-22; 1979.

The effect of physiological concentrations of thiocyanate and/or iodide ions on the in vitro formation of N-methyl-N-nitrosoaniline (NMNA) was studied. The amount of NMNA formed from 0.1 mM N-methylaniline and 0.1 mM potassium nitrite in the presence of 0.5 mM potassium thiocyanate (KSCN) increased 700% compared with the control reaction. Even at the lowest thiocyanate concentration tested (0.005 mM), the effect was considerable. However, the increase in NMNA formation was remarkably higher in the presence of iodide ions: the total percentage increase of NMNA in the presence of 0.015 mM potassium iodide was 240% higher than that in the presence of 0.025 mM KSCN. Tests of the combined effect of thiocyanate and iodide ions on in vitro NMNA formation gave extremely high yields, indicating a cumulative effect. Thiocyanate levels of 0.545 and 1.82 mM have been detected in the saliva of smokers and nonsmokers, respectively. The present results indicate a relatively high rate of NMNA formation in the presence of 0.5 mM thiocyanate. In addition, data are presented that demonstrate that the iodide concentration in human gastric juice could be sufficient to catalyze the nitrosation reaction significantly. (14 refs)

- 79-2614** **ENU-induced Granular Oligodendroglioma in the Rat (Meeting Abstract).** (Eng) Liwnicz, B. H. (Univ. Cincinnati Coll. Medicine, Cincinnati, OH); Mandybur, T. I.; Alvira, M. *J Neuropathol Exp Neurol* 38(3): 329; 1979. (2 refs)

- 79-2615** **The Development of Experimental Brain Tumours: A Sequential Light and Electron Microscope Study of the Subependymal Plate. II. Microtumours.** (Eng) Pilkington, G. J. (Dept. Neurological Studies, Middlesex Hosp. Medical Sch., London W1P 8AA, England); Lantos, P. L. *Acta Neuropathol (Berl)* 45(3): 177-185; 1979.

The cytoarchitecture of the microtumors induced in the rat brain by transplacental administration of N-ethyl-N-nitrosourea (ENU) is described, and the relevance of this experimental model to human neoplasia is assessed. Pregnant BD-IX rats were given a single ip injection of 30 mg/kg ENU on gestation day 15. The offspring were killed at fortnightly intervals between 2 and 20 wk of age. The subependymal plate region adjacent to the lateral ventricles was examined by light and electron microscopy to study the early stages of tumor development. Microtumors, composed of subependymal plate cells, glioblasts, and various glial cells at different stages of maturation, were found in 16-, 18-, and 20-wk-old rats. The most common site for microtumors was the angle of the lateral ventricles between the corpus callosum and caudate nucleus; others were located at the lateral aspect of the ventricles. It is suggested that most, if not all, cerebral gliomas originate from the undifferentiated cells of the subependymal plate: these mitotically active stem cells provide a susceptible target for the carcinogenic stimulus. The morphology of the gliomas is determined by the diverging processes of differentiation and anaplasia, resulting in a pleomorphic cell population. Sequential studies of ENU-induced gliomas may contribute to an understanding of the pathogenesis of gliomas in humans. (22 refs)

- 79-2616** **The Development of Experimental Brain Tumours: A Sequential Light and Electron Microscope Study of the Subependymal Plate. I. Early Lesions (Abnormal Cell Clusters).** (Eng) Lantos, P. L. (Dept. Neurological Studies, Middlesex Hosp. Medical Sch., London W1P 8AA, England); Pilkington, G. J. *Acta Neuropathol (Berl)* 45(3): 167-175; 1979.

The development of transplacentally induced brain tumors in rats is described, and the role of subependymal plate cells in their origin is elucidated. Pregnant BD-IX rats were given a single ip injection of 30 mg/kg N-ethyl-N-nitrosourea on gestation day 15. The offspring were killed at fortnightly intervals between 2 and 20 wk of age. The subependymal plate region adjacent to the lateral ventricles was examined by light and electron microscopy to study the early stages in the development of brain tumors. Abnormal clusters of undifferentiat-

ed subependymal plate cells were found in regions away from the plate from 8 wk of age onward. In addition, focal cellular hyperplasia within the subependymal plate was seen. The clusters, which often occurred around neurones and blood vessels, were thought to represent the earliest morphologically detectable changes in the development of cerebral gliomas. (28 refs)

- 79-2619** **Morphologic and Biochemical Characteristics of Transplantable Neurogenic Tumors Induced by N-Ethyl-N-nitrosourea in Inbred BD IX Rats.** (Eng) Wechsler, W. (Medizinische Einrichtungen, Universität Dusseldorf, Neuropathologisches Institute, Moorenstrasse 5, D-5000 Köln 91, W. Germany); Ramadan, M. A.; Pfeiffer, S. E. *J Natl Cancer Inst* 62(4): 811-817; 1979.

The morphologic and biochemical parameters of three experimental rat tumors, one glioma and two neurinomas, were evaluated during long-term serial transplantation experiments. The tumors were induced transplacentally in inbred BD IX rats by systemic application of N-ethyl-N-nitrosourea (80 mg/kg iv on gestation day 15). Because primary gliomas and neurinomas produced in this way are composed of heterogeneous cell populations, changes in tumor morphology are expected to occur during serial transplantation in syngeneic hosts. These changes were correlated with the expression of two biochemical nervous system markers, S-100 protein and 2',3'-cyclic nucleotide 3'-phosphohydrolase. Several changes were observed during serial transplantation, including increased growth rate (even after 1 passage), preferential growth of anaplastic vs differentiated glial and Schwann's cells, varying degrees of fibrosarcomatous changes

after prolonged serial transplantation, and reduced levels of S-100 protein. In contrast, tumors derived from biochemically differentiated clonal cell lines retained their morphologic and biochemical characteristics to a much greater extent, even after prolonged periods of sc transplantation. 79-2620 Plant Sterols: Role in Large Bowel Cancer (Meeting Abstract). (Eng) Raicht, R. F. (Dept. Medicine, Veterans Admin. Medical Center, New York Univ. Sch. Medicine, New York, NY); Cohen, B. I.; Sarwal, A.; Takahashi, M.; Fazzini, E. *Gastroenterology* 76(5, part 2): 1296; 1979. (no refs)

79-2621 Assessment of Sub-Clinical Zinc-Deficiency for Carcinogenetic and Other Long-Term Studies in Rats. (Eng) Mathur, A. (Dept. Oral Surgery, Faculty Odontology, Univ. Lund, Malmo, Sweden); Wallenius, K.; Abdulla, M. *Arch Oral Biol* 23(12): 1077-1082; 1978.

To determine the influence of zinc on po carcinogenesis, 3-wk-old female Sprague-Dawley rats were fed 0.09 (Group I), 0.77 (Group II), or 3.98 (Group III) micromoles of Zn/kg, and, at 6 wk, were painted 3x/wk with the water-soluble carcinogen 4-nitroquinoline N-oxide. Controls were painted with propylene glycol solvent along. There were no significant differences in wt gain or food consumption between the experimental and control groups, and no animal showed evidence of macroscopic cancer. After 3 wk, the plasma Zn level in Group I was significantly lower than that in Groups II and III, but the levels in Group I later increased to those in Group II. The Cu:Zn ratio in the plasma was significantly higher in Group I than in Groups II and III, and the ratio in Group II was nonsignificantly higher than that in Group III. The liver Zn concentration was always significantly lower in Group I than in Groups II and III. There were no significant differences between the experimental and control animals in each group with respect to the levels of Zn in the plasma or liver or the plasma Cu:Zn ratio. The results suggest that after prolonged intake of the Zn-deficient diet, the plasma Zn level does not accurately reflect the Zn intake and that the Zn concentration in the liver is most affected. The subnormal Zn diet caused subclinical Zn deficiency that could be assessed by laboratory tests. (24 refs)

79-2622 Effect of Storage of Ethyl Methanesulphonate & Hydroxylamine Treated Seeds on Mutation Frequency in Barley *Hordeum vulgare*. (Eng) Singh, R. M. (Dept. Genetics & Plant Breeding, Faculty Agriculture, Banaras Hindu Univ., Varanasi 221 005, India); Agrawal, P. K.; Singh, J.; Singh, B. D.; Singh, R. B. *Indian J Exp Biol* 16(10): 1067-1069; 1979.

Barley seeds were treated with 0.03 M ethyl methanesulphonate and/or 0.08 M hydroxylamine for 6 hr and then planted immediately or stored for 7 or 14 days. Storage reduced germination rate, seedling height, and field survival to some extent, but pollen and ovule fertility were not affected appreciably. However, storage reduced the frequency and spectrum of chlorophyll and viable mutations markedly. Combination treatments had a synergistic effect on mutation induction. (10 refs)

79-2623 Exploratory Monitoring of Air Pollutants for Mutagenicity Activity with the *Tradescantia* Stamen Hair System. (Eng) Schairer, L. A. (Biology Dept., Brookhaven Natl. Lab., Upton, NY, 11973); Van't Hof, J.; Hayes, C. G.; Burton, R. M.; de Serres, F. J. *Environ Health Perspect* 27: 51-60; 1978.

Use of the *Tradescantia* stamen hair genetic system, originally developed for studying the effects of ionizing radiation, for environmental mutagen detection is described. Exposures to the air pollutants SO₂, NO₂, and O₃ and to vapors of mutagens such as 1,2-dibromoethane (DBE) and ethyl methanesulphonate (EMS) demonstrated the usefulness of the system as a detector of chemical mutagens. A significant number of phenotypic changes occurred following exposures to as little as 0.14 ppm DBE. Max sensitivity was obtained with long-term or chronic exposures, because the response increased linearly with duration of exposure up to 21 days. A mobile laboratory designed to support plant culture in the field was used to monitor industrial sites in several states. Environment-controlled growth chambers were installed in a trailer so that both ambient air fumigations and concurrent clean air control exposures could be made. Atmospheric contaminants from petroleum and chemical processing plants generated a significant number of phenotypic pigment changes that were 17%-31% above the control levels; contaminants from steel and copper smelters, automotive combustion products, and photochemical compounds were negative. The *Tradescantia* stamen hair system encompasses the cytogenetic and somatic potential to make it a useful tool for mutagenicity monitoring of ambient air pollution mixtures. (15 refs)

79-2625 Gastric Carcinoma in Dogs Produced by the Combined Use of N-Ethyl-N'-nitro-N-nitrosoguanidine (ENNG) and Gastrin: With Special Refer-

ence to Development of Scirrhus Carcinoma. (Eng) Kurihara, M. (Dept. Gastroenterology, Juntendo Univ., 3-1-3 Hongo, Bunkyo-ku, Tokyo); Shirakabe, H.; Yamaya, F.; Miyasaka, K.; Maruyama, T.; Izumi, T.; Yasui, A.; Kamano, T. *Acta Pathol Jpn* 29(2): 171-176; 1979.

An attempt was made to induce scirrhus carcinoma of the stomach in eight 4-mo-old beagle dogs by the combined administration of N-ethyl-N'-nitro-N-nitrosoguanidine (ENNG) and gastrin. Two dose regimens were used. (1) Four dogs were given 500 ml/day of a 150- μ g/ml ENNG soln po for experimental months (EM) 1-8 and, after a 1-mo interval, 500 ml/day of a 200- μ g/ml soln for 2.5 mo; starting at EM 5, the dogs were inoculated sc with gastrin at a dose of 5 μ g/kg 2x/wk for 4 mo, 10 μ g/kg/day for 2 mo. (2) Four dogs were given 500 ml/day of the 150- μ g/ml ENNG soln for 1 mo, 500 ml/day of the 200 μ g/ml soln for EM 2-8; starting at EM 5, they were inoculated with gastrin at a dose of 5 μ g/kg/day for 1.5 mo, 10 μ g/kg/day for 5 mo. One of four dogs in the first group and two of four in the second group developed gastric carcinoma. One of these three dogs had an annularly infiltrating advanced carcinoma with marked fibrous thickening of the antral wall that resulted in stenosis of the antrum (carcinoma scirrhus). This lesion resembled *linitis plastica* (Bormann's Type IV carcinoma) in the human stomach. Histological examination showed a signet ring cell carcinoma that involved the submucosal, muscular, subserosal, and serosal layers. The foci of gastric carcinoma in the other two dogs did not differ macroscopically or histologically from those produced by ENNG alone. (7 refs)

79-2626 Neuroendocrine Cells in Serially Passaged Rat Stomach Cancers Induced by MNNG. (Eng) Kobori, O. (1st Dept. Surgery, Faculty Medicine, Univ. Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113, Japan); Oota, K. *Int J Cancer* 23(4): 536-541; 1979.

Five gastric carcinomas, induced in inbred Wistar rats by po administration of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 80 mg/liter drinking water for 31 wk), were successfully transplanted to isologous rats. The transplants grew to a size of 10-35 mm in diameter within 8-25 wk of implantation. In one case, serial transplantations were maintained up to the 11th generation, with the occurrence of distant metastasis in the 3rd generation. Histological, histochemical, and ultrastructural comparisons of the original and transplanted tumors revealed that (1) the original tumors were quite well-differentiated, forming papillary or tubular structures, whereas the transplants were more anaplastic and pleomorphic, often showing solid nests; and (2) tumor cells with gastrointestinal differentiation and cells with neuroendocrine differentiation were present and evenly distributed in both the original and the serially transplanted tumors. As it is unlikely that normal and neoplastic neuroendocrine cells were growing side-by-side with and independently of the epithelial neoplastic components, the findings strongly suggest the multidirectional potency of inbred rat stomach carcinoma cells and

the common neoplastic origin of the epithelial and neuroendocrine components. (15 refs)

79-2629 Measurement of Mutagenesis in Mammalian Cells. (Eng) Waldren, C. (Eleanor Roosevelt Inst. Cancer Res., Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO, 80262); Jones, C.; Puck, T. T. *Proc Natl Acad Sci USA* 76(3): 1358-1362; 1979.

An in vitro method for measuring mutagenesis by environmental agents uses stable human-Chinese hamster ovary hybrid cells that have retained a single human chromosome not necessary for cell reproduction. Forward mutations are detected in genes necessary for production of specific human cell-surface antigens. Both mutants form colonies in the presence of specific antisera and complement that destroy the unmutagenized cells. The method is illustrated by tests of X-irradiation, N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), and caffeine. When expressed in terms of number of mutants per 10^4 cells per LD₅₀, MNNG was 8x more potent than X-rays in causing limited marker loss but roughly similar in its ability to cause loss of all or most of the chromosome. Caffeine was without measurable effect. The method permits assessment of lesions that cause loss of all or most of the chromosome as well as various localized gene mutations. The use of this test may help prevent exposure to agents important in cancer and in genetic diseases. (37 refs)

79-2630 The Effect of Bile Acids on Drug Metabolism. (Eng) Kawalek, J. C. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501). *Nutr and Cancer* 1(2): 13-18; 1979.

The effects of cholic acid (CA), chenodeoxycholic acid

(CDC), deoxycholic acid (DOC), and lithocholic acid (LA) on rat microsomal hydroxylases, epoxide hydrolase (EH), and glutathione S-transferase (GSH S-transferase) were studied. In most cases, the bile acids inhibited the microsomal hydroxylase activity, the inhibition being greatest with DOC and varying with substrate, bile acid, and the liver microsome (S9) preparation used for metabolic activation. In one test, LA caused a steady increase in enzymatic activity. EH activity was slightly stimulated by DOC and CA, initially stimulated then markedly decreased by LA, and markedly decreased (50%) by CDC. GSH S-transferase was inhibited by DOC, LA, and CDC and weakly inhibited by CA. These results demonstrate that the presence of bile acids could affect the metabolism of endogenous substrates, carcinogens, and other xenobiotics. (35 refs)

- 79-2631 Effect of Cholesterol Metabolites and Promoting Effect of Lithocholic Acid in Colon Carcinogenesis in Germ-free and Conventional F344 Rats.** (Eng) Reddy, B. S. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Watanabe, K. *Cancer Res* 39(5): 1521-1524; 1979.

The colon tumor-promoting activity of sodium lithocholate (SLC), cholesterol, cholesterol-5 α ,6 α -epoxide (cholesterol epoxide: CE), and cholestane-3 β ,5 α ,6 β -triol (triol) was studied in female Fischer (F-344) conventional and germ-free rats. The germ-free animal system would indicate whether further modification of these compounds by gut microflora is required for tumor promotion. At 7 wk of age, groups of germ-free and conventional rats were given intrarectal instillations of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 2.5 mg/rat 2x/wk for 2 wk) and then intrarectal doses of SLC, cholesterol, CE, or triol (20 mg/rat 3x/wk for 46 wk). Other groups received MNNG for 2 wk and vehicle thereafter for 46 wk or SLC or cholesterol metabolites alone for 48 wk. No tumors were detected in rats given SLC, cholesterol, CE, or triol alone, which suggests that these compounds, or their microbially modified metabolites, were not carcinogenic to colon mucosa under the experimental conditions used. SLC increased MNNG-induced colon tumor incidence in both germ-free and conventional rats. The colon tumor incidence was similar in the MNNG, MNNG + cholesterol, MNNG + CE, and MNNG + triol groups. The results obtained in germ-free rats also indicate that SLC, without being further modified by the gut microflora, acts as a colon tumor promoter. It is concluded that SLC, but not cholesterol, CE, triol, or their microbial products, has a promoting effect on MNNG-induced colon carcinogenesis in rats. (32 refs)

- 79-2632 Response of Two Rodents, *Mastomys natalensis* and *Myiostomys albicaudatus*, to the Pancreatic Carcinogen Azaserine.** (Eng) Roebuck, B. D. (Dept. Pharmacology and Toxicology, Dartmouth Medical Sch., Hanover, NH, 03755); Longnecker, D. S. *J Natl Cancer Inst* 62(5): 1269-1271; 1979.

Two rodent species, *Mastomys natalensis* and *Myiostomys albicaudatus*, were tested for responsiveness to the pancreatic carcinogen azaserine (AS). The animals (aged 28 days) were treated with 30 mg/kg AS ip 1x/wk for 5 wk. They were killed 6 mo after the first AS treatment, and the pancreas was examined for pathological changes. *Myiostomys* was not responsive to AS treatment, but *Mastomys* was the most responsive rodent tested to date. Male *Mastomys* had 84 atypical acinar cell nodules (AACN)/g pancreas, and the females had 75 AACN/g pancreas. In addition to large numbers of AACN in *Mastomys*, 2/4 male animals had acinar cell adenomas. One of these two animals had a circumscribed tumor with marked anaplasia that was regarded as an early carcinoma or a carcinoma in situ. In previous studies, male Wistar rats had 51 AACN/g pancreas and the females had 20 AACN/g pancreas. (8 refs)

- 79-2633 Neuraminidase Effect on the Growth of a Transplantable Nickel Sulfide-induced Rat Tumor.** (Eng) Abandowitz, H. M. (Dept. Biomedical Sciences, Univ. Guelph, Guelph, Ontario, Canada). *Jpn J Med Sci Biol* 31(5/6): 421-424; 1978.

The immunostimulatory potential of a weakly immunogenic nickel sulfide induced fibrosarcoma was determined after treatment of the tumor cells with *Vibrio cholerae* neuraminidase (VCN). The cells were exposed to 50 IU VCN/5 x 10⁶ cells/ml phosphate-buffered saline at 37 C for 30 min. Then, 1 x 10⁶ viable cells were inoculated sc in the leg of two groups of four highly inbred Fischer (F344) rats (8-10 wk old). The VCN-tumor-immunized rats, which remained free of palpable tumors for 32 days, were rechallenged sc in the opposite leg with 5 x 10⁵ freshly harvested viable untreated tumor cells. Administration of VCN-treated tumor cells rendered 50% of the rats resistant to a subsequent challenge with untreated viable tumor cells. When tumors did appear in two VCN-tumor-immunized rats, their time of appearance was delayed by 8 and 11 days and their growth was retarded (12.9 mm in immunized rats, compared with 30.5 mm in control rats). Tumors were palpable in all control rats 4 days after injection of untreated tumor cells. These findings provide preliminary evidence of the potential of VCN enhancement in tumor immunogenicity. (13 refs)

- 79-2634 Basal Cell Carcinoma of the Scrotum in a Former Employee of a Japanese Mustard Gas Factory.** (Jpn) Inada, S. (Dept. Dermatology, Hiroshima Univ. Sch. Medicine, Kasumi, Hiroshima 734, Japan); Yamura, T.; Takiyama, W.; Kamitsuna, A.; Nishimoto, Y. *Jpn J Cancer Clin* 25(1): 67-70; 1979.

In 1977, a basal cell carcinoma of the scrotum was diagnosed in a 72-yr-old man who had worked in a mustard gas factory from 1933 to 1945. He had pleuritis at age 28 and chronic bronchitis at age 62 as a result of exposure to mustard gas;

a slightly differentiated adenocarcinoma of the stomach was resected at age 71. During the patient's employment at the poison gas factory, mustard gas permeated through his protective clothing and often caused acute sinusitis, bronchitis, and dermatitis in areas where perspiration collected. In 1974 and 1975, two of the hyperkeratotic eruptions that occurred on the skin of the patient's trunk and lower extremities were diagnosed histopathologically as Bowen's disease. The mustard gas was considered to be the cause of the Bowen's disease and the basal cell carcinoma. (34 refs)

- 79-2635 Epidermal Carcinogenicity of Bis(2,3-epoxycyclopentyl)ether, 2,2-Bis(p-glycidyloxyphenyl)propane, and m-Phenylenediamine in Male and Female C3H and C57BL/6 Mice.** (Eng) Holland, J. M. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Gosslee, D. G.; Williams, N. J. *Cancer Res* 39(5): 1718-1725; 1979.

The systemic toxicity and skin carcinogenicity of bis(2,3-epoxycyclopentyl)ether (BECE), 2,2-bis(p-glycidyloxyphenyl)propane (BGOP), and m-phenylenediamine (PD) were compared with those of benzo(a)pyrene by application to the skin of male and female C3H and C57BL/6 mice 3x/wk for 24 mo. BECE and BGOP were also applied as an equal parts mixture to determine whether the materials would interact as skin carcinogens. A comparison of dose responses showed that benzo(a)pyrene was 107×10^3 , 161×10^3 , and 51×10^3 more potent as a skin carcinogen than BECE, BGOP, and their mixture, respectively. PD was not carcinogenic in the skin of either strain at the max exposure rate allowed by systemic toxicity. The two inbred mouse strains used exhibited a constant ratio of sensitivity to the induction of epidermal cancer by diverse chemical agents. Statistical analysis of this difference for various compounds at different dose rates revealed that C57BL/6 mice were 2.4 times more sensitive to epidermal carcinogenesis than C3H mice under identical circumstances of exposure. It is suggested that when carcinogenicity is assessed on a relative basis, the observed constancy in the response ratio would enable these two inbred strains to be used interchangeably. The choice of strain would affect the sensitivity of the assay significantly, but this would become important only in the assay of extremely weak carcinogens. (17 refs)

- 79-2636 The Role of Dietary Fiber in Colon Tumorigenesis Induced by Dimethylhydrazine in the Rat (Meeting Abstract).** (Eng) Barbolt, T. A. (Albany Medical Coll., Union Univ., Jackson, TN, 38301). *Diss Abstr Int [B]* 39(9): 4282-4283; 1979. (no refs)

- 79-2637 Induction of Sister-Chromatid Exchanges (SCE) in Human Leukocytes by Cyclic Nitroso-Compounds (Meeting Abstract).** (Eng) Ho, T. (Biology

Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Tipton, S. C.; Epler, J. L. *In Vitro* 15(3): 209; 1979. (no refs)

- 79-2638 Hodgkin's Disease as a Complication of Crohn's Disease.** (Eng) Hecker, R. (Gastroenterology Unit, Royal Adelaide Hosp., Adelaide, Australia 5000); Sheers, R.; Thomas, D. *Med J Aust* 2(13): 603; 1978.

The case report of a 32-yr-old man who developed intestinal Hodgkin's disease in association with a 10-yr history of colorectal Crohn's disease is presented. Although the association could have been coincidental, the history of Crohn's disease, the presence of histocompatibility antigens HLA-A1 and HLA-B5, and 5 yr of exposure to azathioprine could have been involved. Hodgkin's disease (mixed cellularity type) involved the celiac nodes, paracolic nodes, and the sites of three skip lesions in the ileum, transverse colon, and rectosigmoid junction. (5 refs)

- 79-2639 Reticulum Cell Sarcoma in Azathioprine-treated Systemic Lupus Erythematosus.** (Eng) Hehir, M. E. (Royal Postgraduate Medical Sch., London, England); Sewell, J. R.; Hughes, G. R. *Ann Rheum Dis* 38(1): 94-95; 1979.

The development of a reticulum cell sarcoma in the lung of a 43-yr-old woman who had received 18 mo of azathioprine treatment for systemic lupus erythematosus (SLE) is described. Only two other cases of this association have been reported. Tumor induction may be a possible hazard of immunosuppressive therapy in SLE patients. (4 refs)

- 79-2640 Vasopressin Stimulation of Mouse 3T3 Cell Growth.** (Eng) Rozengurt, E. (Imperial Cancer Res. Fund, P. O. Box 123, Lincoln's Inn Fields, London WC2A 3PX, England); Legg, A.; Pettican, P. *Proc Natl Acad Sci USA* 76(3): 1284-1287; 1979.

In tests conducted to determine whether substances that promote Na⁺ entry can be mitogenic for quiescent cells, vasopressin was shown to be a potent mitogen for Swiss mouse 3T3 cells. The hormone [1-10 nanograms (ng)/ml] caused a striking shift of the dose-response curve for the effect of serum on thymidine incorporation by cultures of 3T3 cells arrested in the G₁/G₀ phase of the cell cycle. In the absence of added serum, the effect of vasopressin on DNA synthesis was greatly potentiated by insulin, epidermal growth factor, and a factor isolated from medium conditioned by simian virus 40-infected baby hamster kidney cells. The mitogenic effect of vasopressin was dependent on time and hormone concentration. In the presence of insulin, the half-maximal effect elicited by the peptide was obtained at 0.6 ng/ml. [Arg]vasopressin and [Lys]vasopressin were equally potent.

The vasopressins were 10^3 -fold more potent than oxytocin. In the presence of a low (2.5%) concentration of serum, the vasopressins stimulated cell proliferation. (21 refs)

- 79-2641 Dissociation of α -Macrofetoprotein and α -Fetoprotein Production During Experimental Injury.** (Eng) Hudig, D. (Dept. Medicine M-013, Univ. California, San Diego, La Jolla, CA, 92093); Sell, S.; Newell, L.; Smuckler, E. A. *Lab Invest* 40(2): 134-139; 1979.

The concentrations of two major fetal serum proteins of the rat, α -macrofetoprotein (AMF) and α -fetoprotein (AFP), were measured following administration of croton oil (0.1 ml injected into a hind footpad), carbon tetrachloride (0.35 ml x 2 ip, or single dose of 25 μ g/100 g po), galactosamine (200-800 mg/kg ip, 1 or 2 doses), or ethionine (0.64 nanomole/100 g ip) and after 70% partial hepatectomy. The greatest elevations in AMF occurred in animals given croton oil or ip CCl_4 and after partial hepatectomy. These concentrations were similar to max fetal rat concentrations at 20 days of gestation. The greatest AFP concentration was seen after partial hepatectomy, 800 mg/kg galactosamine, and po CCl_4 . These concentrations were well below those of 20-day rat fetuses. SGOT values, which are indicative of the degree of lytic hepatic injury, were greatest in animals given po CCl_4 and 800 mg/kg galactosamine. When both AMF and AFP concentrations were elevated, AMF appeared to be an acute-phase reactant, whereas AFP elevations occurred later and were associated with hepatic proliferation. Apparently, the production of AMF and AFP is under completely independent regulation in the adult rat. (36 refs)

- 79-2642 Effects of the Co-mutagen Norharman in Rats.** (Eng) Murasaki, G. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Miyata, Y.; Shirai, T.; Arai, M.; Kawachi, T.; Ito, N. *Toxicol Lett* 3(3): 157-161; 1979.

The acute and subacute toxic effects of the comutagen norharman (NH) were determined in male Fischer rats. Animals were fed diets containing 1,500 ppm NH for 28 days, and 3 or 6 animals were killed for examination on days 0, 1, 3, 7, 14, 21, and 28. During NH administration, the body wt and food and water intakes of the rats decreased gradually, but kidney wt and blood urea nitrogen levels increased significantly (the latter was 107.3 mg/dl on day 28). NH caused a segmental coagulative necrosis of the tubular epithelium of the kidney that increased in severity and extent with the duration of treatment, but glomerular changes were negligible. In the testis, the germinal epithelium showed decreased spermatogenic activity after day 7. NH had no detectable effects on other organs. (9 refs)

- 79-2643 Effects of Cannabinoids on Host Resistance to *Listeria monocytogenes* and Herpes Simplex**

Virus. (Eng) Morahan, P. S. (Dept. Microbiology, Medical Coll. Virginia, Virginia Commonwealth Univ., Richmond, VA, 23298); Klykken, P. C.; Smith, S. H.; Harris, L. S.; Munson, A. E. *Infect Immun* 23(3): 670-674; 1979.

An attempt was made to determine whether cannabinoids decrease host resistance to infections with *Listeria monocytogenes* and herpes simplex virus type 2 (HSV-2). Host resistance was measured by changes in the 50% lethal dose of the pathogen in cannabinoid-treated and control mice. The effect of cannabinoids on resistance to *L. monocytogenes* was dose-dependent. Δ^9 -Tetrahydrocannabinol, at doses of 38, 75, and 150 mg/kg, suppressed resistance to infection by 10-, 17-, and 657-fold, respectively. Marijuana extract was less active, but it significantly reduced resistance to *L. monocytogenes* at all tested doses. Resistance to systemic HSV-2 infection was decreased 96-fold by Δ^9 -tetrahydrocannabinol, although marijuana extract was inactive. The doses and regimen of treatment with cannabinoids that produced significant decreases in host resistance were similar to those that caused suppression of delayed-type hypersensitivity to sheep RBC. The possible mechanisms and public health aspects of the decreased host resistance produced by marijuana extract and its cannabinoids are presented. (22 refs)

- 79-2644 Comparative Study of Liver Enlargement Induced by Various Chemicals.** (Eng) Fukuhara, M. (Inst. Public Health, 6-1 Shirokanedai 4-chome, Minato-ku, Tokyo 108, Japan); Takabatake, E. *J Pharmacobiodyn* 1(3): 153-159; 1978.

The ability of several chemicals to induce hepatomegaly was compared after short-term ip or dietary treatment of male Wistar-SLC rats. Polychlorinated biphenyls were the most effective, followed by 3-methylcholanthrene, furylfuramide, phenobarbital, and di-2-ethylhexyl phthalate. The chemicals had different effects on hepatic cytochrome P-450 concentration, aminopyrine N-demethylase activity, lipid and glycogen levels, and total amounts of DNA or total cell number. (23 refs)

- 79-2645 Induction of Rat Hepatic Epoxide Hydratase by Dietary Antioxidants.** (Eng) Kahl, R. (Dept. Pharmacology, Univ. Mainz, 6500 Mainz, W. Germany); Wulff, U. *Toxicol Appl Pharmacol* 47(2): 217-227; 1979.

The effects of supplementation of the diet with the antioxidants butylated hydroxytoluene (BHT), butylated hydroxyanisole, or ethoxyquin (each, 0.005%-0.5% of the diet for 14 days) on rat hepatic epoxide hydratase (EH) activity were studied in male Sprague-Dawley rats. All three compounds increased liver EH activity. The increase was obvious at the 0.1% dietary level and amounted to 200%-400% at 0.5%. Increased activity was accompanied by an increase of the EH band in sodium dodecyl sulfate-polyacrylamide gels, indicat-

ing induction of the enzyme. Ethoxycoumarin deethylase activity and cytochrome b, concentrations were moderately elevated, but cytochrome P-450 concentrations and aryl hydrocarbon hydroxylase (AHH) activity remained at control levels. Preferential inhibition of monooxygenase activity by metyrapone and not 7,8-benzoflavone, as well as the increased affinity of the reduced cytochrome P-450 for metyrapone as a ligand, indicated that the cytochrome P-450 population after BHT treatment was similar to that found after phenobarbital treatment. The antioxidants had no in vitro effect on EH activity and inhibited monooxygenase activity only in phenobarbital-stimulated microsomes but not in 3-methylcholanthrene (3-MC)-stimulated microsomes. Combined treatment with dietary antioxidants and 3-MC (3 doses of 20 mg/kg, ip) resulted in a marked induction of EH activity, but the 3-MC-mediated increase in AHH activity was partially depressed. Covalent binding of tritiated benzo(a)pyrene to calf thymus DNA was less effectively catalyzed by liver microsomes from animals fed antioxidants. The depression of covalent binding was marked after combined treatment with antioxidants and 3-MC. The shift in the microsomal enzyme pattern caused by the antioxidants may be related to their inhibitory effects on chemical carcinogenesis. (39 refs)

- 79-2646** Mutagenic Activities of 1,2,7,8-Diepoxyoctane in Chinese Hamster Lung Cells. (Eng) Huang, S. L. (Lab. Environmental Mutagenesis, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC, 27709). *J Environ Pathol Toxicol* 2(3): 587-599; 1979.

The mutagenicity of 1,2,7,8-diepoxyoctane (DEO) to Chinese hamster lung cells and its ability to form adducts with nucleotides were investigated. 6-Thioguanine resistance and chromosome aberrations were used as markers for mutagenicity. DEO was found to be genetically active and to form adducts readily with radiolabeled nucleotides, as demonstrated by thin-layer chromatography of DEO/nucleotide mixtures. The continuous disappearance of cells carrying chromosome aberrations from the cell populations was observed. Based on the expected frequency, cell death can be interpreted as a result of chromosome aberrations. The mutagenic specificity of DEO was apparently related to its ability to bind with DNA. (24 refs)

- 79-2647** Effect of Dose on Urinary Bladder Carcinogenesis Induced in F344 Rats by N-[4-(5-Nitro-2-furyl)-2-thiazolyl]formamide. (Eng) Arai, M. (First Dept. Pathology, Nagoya City Univ. Medical Sch., Nagoya 467, Japan); Cohen, S. M.; Jacobs, J. B.; Friedell, G. H. *J Natl Cancer Inst* 62(4): 1013-1016; 1979.

The effect of dose on N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT)-induced bladder carcinogenesis was evaluated in weanling male F344 rats. The rats were fed a diet

containing of 0.1%, 0.05%, 0.01%, 0.005%, 0.001%, or 0.0005% FANFT for 30 wk and then a control diet for 22 wk. A control group received only the control diet throughout the experiment. Papillary tumors were present at the higher doses, hyperplasia of various degrees of severity was present at the intermediate doses, and minimal hyperplasia was observed in 4/16 rats at the 0.005% dose; no mucosal abnormalities were observed at the two lower doses or in the control group. Bladder epithelium from selected animals was examined by scanning electron microscopy (SEM) after 10 wk and again at the end of the experiment. Hyperplastic mucosa with pleomorphic microvilli similar to that previously demonstrated for 0.2% FANFT was observed at 10 wk in rats fed 0.1% FANFT. Hyperplastic mucosa with pleomorphic microvilli was also observed at 52 wk in rats fed 0.1% and 0.05% FANFT. Hyperplastic mucosa without pleomorphic microvilli was observed in rats fed 0.01% and 0.005% FANFT. The bladder appeared normal by light microscopy and SEM at the two lower doses and in the control group at both the 10- and 52-wk intervals. A dose relationship was thus demonstrated for FANFT-induced bladder carcinogenesis in male F344 rats, and more severe surface changes were observed by SEM as the dose increased. (10 refs)

- 79-2648** Procarbazine-induced Specific-Locus Mutations in Male Mice. (Eng) Ehling, U. H. (Abteilung für Genetik, Gesellschaft Strahlen- und Umweltforschung, 8042 Neuherberg, W. Germany); Neuhauser, A. *Mutat Res* 59(2): 245-256; 1979.

The specific locus method was used to determine the ability of procarbazine (single dose of 200, 400, 600, or 800 mg/kg ip) to induce mutations in pre- and postmeiotic germ cells of hybrid (101/E1 x C3H/E1)_{F1} male mice. The lowest dose that significantly increased the mutation frequency in As spermatogonia over the control frequency was 400 mg/kg; the corresponding dose for the postspermatogonial germ-cell stages was 600 mg/kg. The responses were linear with dose up to 600 mg/kg. The variations in mutation rates among the seven loci between the lowest (*a* locus) and highest (*p* locus) was 12-fold. Only 24% of the procarbazine-induced specific locus mutations in the As spermatogonia were lethal in the homozygous condition. The mutations appeared to be due primarily to base-pair changes. The doubling dose of procarbazine in As spermatogonia (the dose needed to induce as many mutations as occur spontaneously) was 114 mg/kg. The therapeutic dose for procarbazine in humans is 215 mg/kg. If humans were as sensitive to the drug as mice, 22 mutations per million children would be expected to occur as a result of procarbazine treatment. (29 refs)

- 79-2649** *cis*-Platinum(II) Diamine Dichloride Causes Mutation, Transformation, and Sister-Chromatid Exchanges in Cultured Mammalian Cells. (Eng) Turn-

bull, D. (Biology Branch, Carcinogenesis Res. Program, NCI, NIH, Bethesda, MD, 20014); Popescu, N. C.; DiPaolo, J. A.; Myhr, B. C. *Mutat Res* 66(3): 267-275; 1979.

The ability of *cis*-platinum(II) diammine dichloride (PDD) to induce sister chromatid exchanges (SCE's), mutation, and morphologic transformation in V79 chinese hamster cells and in secondary Syrian hamster embryo cells (HEC) was investigated. PDD, at 0-10 $\mu\text{g/ml}$ and 0-0.5 $\mu\text{g/ml}$, respectively, produced a dose-dependent toxicity in both V79 cells and HEC. It also caused a significant, dose-dependent increase in SCE frequency in V79 cells relative to untreated controls. The increase was more than threefold at 1.0 $\mu\text{g/ml}$ PDD and eightfold at 5 $\mu\text{g/ml}$. Chromatid and chromosome aberrations were induced within 6 hr of treatment of V79 cells with 5 $\mu\text{g/ml}$ PDD, and thioguanine-resistant mutants were induced in a dose-dependent manner. Expression of resistance was complete within 2 days following treatment with 2.5 $\mu\text{g/ml}$ and within 5 days after $\mu\text{g/ml}$. Morphologically altered colonies were found in HEC cultures treated with PDD, an approx linear relation being observed between drug concentration and the frequency of transformed colonies per survivor for all doses tested. The data suggest that PDD is a potential carcinogen. (17 refs)

79-2650 Comparison of Level, Duration of Exposure, Housing, and Source of Animal on Diethylstilbestrol-induced Mammary Tumorigenesis in C3H Mice (Meeting Abstract). (Eng) Norvell, M. J. (Natl. Center Toxicological Res., Jefferson, AR); Farmer, J. H. *J Toxicol Environ Health* 4(2/3): 492; 1978. (no refs)

79-2651 Carcinogenic Effects of Diethylstilbestrol in Male Syrian Golden Hamsters and European Hamsters. (Eng) Reznik-Schuller, H. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501). *J Natl Cancer Inst* 62(4): 1083-1088; 1979.

The tumorigenic effects of sc-implanted diethylstilbestrol (DES) on male Syrian golden hamsters and European hamsters were compared. The latter species have been found to be highly sensitive to various chemical carcinogens. Each animal received an sc implant of a pellet containing 25 mg DES; this implant was replaced every 5 mo. The adenohypophyses, kidneys, and testes of both species showed neoplastic responses to DES treatment. European hamsters were more sensitive than Syrian hamsters, inasmuch as the European hamsters had a higher tumor incidence. The testicular tumors were all Leydig cell adenomas, and they seemed to depend on the coincident occurrence of hypophyseal neoplasms (all composed of gonadotropic cells). Of the European hamsters tested, 29% also developed liver tumors (hepatocellular adenomas, carcinomas, and cholangiocarcinomas). These lesions were not found in the Syrian hamsters. (13 refs)

79-2652 Induction of Lymphomas by Urethane in Combination with Diethylstilbestrol in CFLP Mice.

(Eng) Bojan, F. (Inst. Hygiene and Epidemiology, Univ. Medical Sch., Nagyerdei krt 98, H-4012 Debrecen, Hungary); Redai, I.; Gomba, S. *Experientia* 35(3): 378-379; 1979.

The combined carcinogenic effect of urethan (UT) and diethylstilbestrol (DES) was studied in CFLP mice. Adult CFLP mice received a single dose of 1,000 mg/kg UT ip and 50 mg/kg DES sc either simultaneously or at a 14-day interval. Animals were autopsied when they appeared ill or within 300 days. Induced lymphomas were transplanted (5×10^6 cells ip) into newborn mice of several strains. Autopsy revealed two tumor types: malignant lymphomas in some mice in groups treated with DES + UT and multiple lung tumors in all animals treated with UT, with or without DES. DES + UT after 14 days induced lymphomas in 4/22 mice; DES + UT simultaneously induced lymphomas in 8/25 mice; UT + DES after 14 days induced lymphomas in 11/25 mice. UT alone induced lymphomas in 0/48 mice and DES alone in 2/40. The induced lymphomas were successfully transplanted in 6/10 newborn CFLP mice. The passage of lymphomas from CFLP mice into newborn BALB/c, C3H/He-mg, CBA/Ca, and AKR mice was also successful. All the induced and transplanted lymphomas were lymphoblastic lymphosarcomas. Intracellular A-type and extracellular C-type virus particles were detected in the tumors by electron microscopy. These results demonstrate that the carcinogenic potential of UT and DES may be enhanced in combination. (9 refs)

79-2653 Effect of In Utero Exposure to Diethylstilbestrol on the Immune Response in Mice. (Eng)

Luster, M. I. (Natl. Inst. Environmental Health Sciences, NIH, PO Box 12233, Research Triangle Park, NC, 27709); Faith, R. E.; McLachlan, J. A.; Clark, G. C. *Toxicol Appl Pharmacol* 47(2): 279-285; 1979.

The effects of a single administration of diethylstilbestrol (DES) in the prenatal period on cellular and humoral immunity were studied in Swiss-Webster (CD-1) mice. Mice were exposed to DES through maternal dosing (0.1 mg/kg sc) on gestation day 16, and they were evaluated at age 7-9 wk. When sensitized mice were challenged with purified protein derivative (PPD), only treated females had a significant reduction in delayed hypersensitivity reactions, but males showed a similar trend. Spleen cells from male and female DES-exposed mice had a significantly diminished response to concanavalin A compared with sex-matched controls. DES treatment had no effect on serum IgG2 levels, but it decreased serum IgG1 levels in females and increased these levels in males. IgM and IgA were also decreased in treated females, but they were within the normal range in male mice. In the antibody plaque assay, DES treatment did not significantly alter the response to sheep RBC. However, *Escherichia coli* 0127 lipopolysaccharide (LPS) plaque-forming cells were significantly suppressed in treated females and increased in treated males. This enhanced LPS response was due to IgM

(19S) antibodies. These results indicate that DES slightly suppressed cell-mediated immune function in both males and females. There was a sex specificity in humoral immune function, with enhanced antibody responses to a T-independent antigen in males and either no effect or slight suppression in females. (28 refs)

A comparison of 24 men exposed to diethylstilbestrol in utero with 24 age-matched controls revealed no differences in psychosexual history, medical history, genital examination, or semen analysis between the two groups. (9 refs)

- 79-2655** Long-Term Estrogenization in Mammals. I. Histopathology of Kidney, Bladder, Adrenals, and Gonads; Polydipsia; Body Weight; and Serum Levels of Corticosterone and Testosterone in Estrogenized Marsh Mice. (Eng) Bryson, G. (Dept. Psychology, Univ. California at Santa Barbara, Santa Barbara, CA 93106); Bischoff, F. *Res Commun Chem Pathol Pharmacol* 23(3): 575-595; 1979.

The dipsogenic effects of single sc injections of estrogen (5 mg) and estradiol (0.34 mg as estradiol cypionate) were studied in Marsh mice. Histopathologic changes in the bladder (eg, cystitis, metaplasia, hypertrophy inflammation, ulceration) occurred following the onset of polydipsia in 14/51 mice given estrogen and 29/52 mice given estradiol. Histopathology of the kidney (eg, pyelonephritis, ischemic necrosis, interstitial nephritis) occurred less frequently, indicating that bladder pathology preceded kidney pathology. The polydipsia was more intense (up to 250% over control intake) in animals housed in metal cages with floor screens than in those housed in plastic cages. Water intake by untreated controls was unaffected by housing. Water intake by estrogenized mice was always significantly greater than that by untreated controls. Estrogen produced a body wt loss that was not recovered except in the case of the youngest females (2.5 mo at the time of estrogen injection). Estrogenization markedly increased corticosterone and decreased testosterone levels in the serum. The levels of these hormones were negatively correlated in the estrogenized mice, whereas the testosterone levels were positively correlated with testis wts. (23 refs)

- 79-2658** Induction of Pituitary and Mammary Tumors in Male, "Fale" and Female Rats by Either DMBA, Estradiol Implant or Combined Treatment. (Eng) Kao, K. J. (Dept. Physiology and Biophysics, Univ. Illinois, Urbana, IL 61801); Ramirez, V. D. *Proc Soc Exp Biol Med* 160(3): 296-301; 1979.

The endocrinologic basis for the sex difference in the response of rats to 7,12-dimethylbenz(a)anthracene (DMBA) carcinogenesis was studied in Sprague-Dawley rats. Pellets containing 5.06 mg β -estradiol-3-benzoate (E_2) crystals were implanted sc into 45-day-old intact or neonatally castrated males and females; DMBA (5 mg/ml of a 1 ml emulsion) was injected at 50 days. The incidence of DMBA-induced mammary tumors was 50% in intact females vs 16.7% in intact males. In castrated male and female rats, the tumor incidence increased from 0% to 30% and 44.4%, respectively, after E_2 implantation. E_2 did not increase the mammary tumor incidence in intact animals. High serum prolactin levels were induced by E_2 in males and females, and pituitary tumors were found in almost all animals with E_2 implants. In females implanted with E_2 at 45 days, follicle stimulating hormone and luteinizing hormone levels were normal. The increase in serum prolactin levels in these rats was effectively reduced by sc injection of α -bromoergocriptine (400 μ g) 96 days after E_2 implantation. The results suggest that long-term, low-dose administration of estrogenic substances might increase the risk of pituitary tumor induction in humans. (38 refs)

- 79-2659** Combined Epithelial and Sarcomatous Elements in a Liver Cancer Associated with Oral Contraceptive Use. (Eng) Ladaga, L. (Medical Center Hosp., 600 Gresham Dr., Norfolk, VA 23507); Kay, S.; Melcher, M.; King, J. N. *Am J Surg Pathol* 3(2): 185-190; 1979.

The occurrence of a rare malignant tumor in a 35-yr-old woman who had used oral contraceptives (norethindrone 2 mg and mestranol 0.10 mg) continuously for 12 yr is reported. Use of the contraceptives was discontinued 3 yr

prior to admission because of hepatic enlargement. The liver spontaneously regressed in size and remained stable until 3 mo prior to admission, at which time hepatomegaly, jaundice, and pruritis were noted. Hypovolemia and clotting abnormalities were corrected and an exploratory laparotomy revealed a massive ip hemorrhage secondary to a ruptured tumor on the inferior aspect of the left lobe of the liver. The patient died 19 days after admission, and postmortem examination revealed a bimorphic tumor replacing 50% of the liver and consisting of moderately differentiated hepatocellular carcinoma and sarcoma. The absence of cellular transition and of a distinct metastatic pattern implied separate primaries with collision rather than common ancestry or dedifferentiation. A sister of the patient had a histologically proved hepatic adenoma associated with the use of oral contraceptives. (19 refs)

79-2660 Oral Contraceptive Administration and Hepatocellular Neoplasms in the Rat: Preliminary Results (Meeting Abstract). (Eng) Klein, K. M. (Dept. Pathology, Coll. Medicine and Dentistry New Jersey-New Jersey Medical Sch., Newark, NJ) *Gastroenterology* 76(5, part 2): 1288; 1979 (no refs)

79-2661 Intravaginal Estrogen Creams and Endometrial Cancer. No Causal Association Found. (Eng) Horwitz, R. I. (Robert Wood Johnson Clinical Scholar Program, Yale Univ. Sch Medicine, 333 Cedar St., New Haven, CT 06510); Feinstein, A. R. *JAMA* 241(12): 1266-1267; 1979.

In two case-control studies of estrogens and endometrial cancer, 187 women with endometrial cancer and 137 matched controls were asked about previous use of intravaginal estrogen creams. The two studies used different sampling methods to select cases and controls. In one study, 7% of the women with endometrial cancer reported using estrogen creams compared with 8% of the controls. In the second study, 9% of the cancer patients reported having used estrogen creams compared with 10% of the controls. The odds ratio in the first study was 0.90 and that in the second study was 0.82. In neither study were the differences significant. The results do not support an association between the use of intravaginal estrogen creams and endometrial cancer. (10 refs)

79-2662 Contraceptive Steroids and Breast Cancer. (Eng) Spencer, J. D. (Imperial Cancer Res. Fund Breast Cancer Unit, Guy's Hosp., London SE1 9RT, England); Millis, R. R.; Hayward, J. L. *Br Med J* 1(6119): 1024-1026; 1978.

The prognosis and pathological findings in 44 breast cancer

patients who had taken contraceptive steroids during the year before diagnosis (study group) were compared with those in 44 breast cancer patients who had never used contraceptive steroids (controls) matched for age and parity. All of the patients in the study group had been using products containing ≤ 50 μ g estrogen. No appreciable difference in tumor size, histological type, grade of malignancy, or lymphoplasmacytic infiltration was found between the study group and controls. Moreover, the degree of sinus histiocytosis in unaffected lymph nodes was similar in each group. Fewer patients in the study group had axillary lymph node infiltration, and the mean number of affected nodes in these patients was less than that of controls. In patients with axillary node disease, the recurrence rate in controls was significantly higher than that in the study group. One interesting and unexplained finding was that the mothers of nine patients in the study group had had breast cancer compared with none in the control group. This difference merits further investigation in a larger series. Overall, the findings suggest that recurrence rate and mortality are unlikely to be increased in patients who have taken contraceptive pills before breast cancer is diagnosed; rather, the opposite seems to be the case. - 79-2665 **γ -Ray-enhanced Reactivation of UV-irradiated Adenovirus in Normal Human Fibroblasts.** (Eng) Jeeves, W. P. (Dept. Biology, McMaster Univ., Hamilton, Ontario L8s 4J9, Canada); Rainbow, A. J. *Mutat Res* 60(1): 33-41; 1979.

The γ -ray-enhanced reactivation (γ RER) of UV-irradiated human adenovirus type 2 (Ad2) in several normal human fibroblast lines was examined. The frequency of cells positive for Ad2 viral structural antigen (VAg) was reduced in pre- γ -irradiated cultures 48 hr after infection with unirradiated virus, whereas VAg was reduced to a significantly lesser extent or even increased in preirradiated cells 48 hr after infection with UV-irradiated virus. Preirradiation of cells immediately prior to infection with UV-irradiated virus markedly enhanced the survival of VAg production. The av value for the γ RER factor rose with increasing UV dose to the virus and with increasing γ -ray dose to the cells. Examination of VAg expression at various times after infection indicated that preirradiation of the cells with γ -rays prior to infection with UV-irradiated virus led to an earlier onset and/or increased rate of VAg synthesis. This enhancement of VAg production from a UV-damaged template may have resulted from an inducible DNA-repair mechanism in human fibroblasts that may or may not be error-prone. (18 refs)

- 79-2666 **Photosensitivity and DNA Repair. Possible Relationship Between Xeroderma Pigmentosum and Cockayne's Syndrome.** (Fre) Lafforet, D. (Unite de Recherche d'Hepatologie Infantile I.N.S.E.R.M., U. 56, 94270 Bicetre, France); Dupuy, J. M. *Arch Fr Pediatr* 35(10, Suppl): 65-74; 1978.

DNA repair following UV irradiation and phytohemagglutinin (PHA) transformation of lymphocytes were studied in 12 children (7 boys, 5 girls aged 3-12) with photosensitivity diseases [xeroderma pigmentosum (XP:6), Cockayne's syndrome (CS:2), XP-CS (2), and Bloom's syndrome (2)]. These diseases are rare and are transmitted genetically by autosomal recessive genes. DNA

repair was studied in lymphocytes irradiated with 30, 90, or 300 ergs/mm². After 30 ergs/mm², DNA repair, as measured by ³H-thymidine uptake, was normal. After 300 ergs/mm², however, the lymphocytes from all but two of the patients (1 with XP and 1 with XP-CS) showed diminished DNA repair. Reaction to stimulation by PHA was diminished in lymphocytes in 5/6 XP patients, 4/4 CS and XP-CS patients, and 1/2 patients with Bloom's syndrome. The immune deficit observed in the XP patients and in those with CS or XP-CS suggests that these diseases have a common origin. (19 refs)

- 79-2668 **Induction of Sister Chromatid Exchanges in Human Cells by Fluorescent Light.** (Eng) Monticone, R. E. (Section Cellular Aging and Genetics, Lab. Cellular and Molecular Biology, Gerontology Res. Center, Natl. Inst. Aging, NIH, Baltimore, MD 21224); Schneider, E. L. *Mutat Res* 59(2): 215-221; 1979.

The bromodeoxyuridine-differential staining technique was used to examine the induction of sister chromatid exchanges (SCE's) by fluorescent light (FL) in human fetal lung fibroblasts (IMR-90). Exposure of these cells in media to FL increased the SCE frequency from a background level of 8.5 to 20.5 SCE's/cell. Cellular replication kinetics were also inhibited by FL exposure. Exposure of cells to FL in phosphate-buffered saline resulted in a twofold increase in SCE levels and an increased inhibition of cell replication, indicating that culture media may have a protective effect. Determinations of SCE frequencies with blocking filters indicated that the FL wavelengths responsible for SCE induction were in the near-UV spectrum between 300 and 390 nanometers. Culturing cells in media that had been exposed to FL resulted in a significant increase in SCE levels, 14.5 vs 7.5, demonstrating the contribution of media photoproducts to SCE induction. The role of media photoproducts was further reinforced by the significant decline in FL-induced SCE found in cells cultured in medium deficient in three known photosensitizers (phenol red, tetracycline, and riboflavin) for 2-3 wk prior to exposure. Since SCE's have been shown to be a sensitive indicator of DNA damage, these results indicate that FL can

induce genetic damage in human cells. These findings are of importance to investigators culturing cells in laboratories illuminated with FL. (30 refs)

- 79-2669 Single-Strand Breaks in DNA During Repair of UV-induced Damage in Normal Human and Xeroderma Pigmentosum Cells as Determined by Alkaline DNA Unwinding and Hydroxyapatite Chromatography. Effects of Hydroxyurea, 5-Fluorodeoxyuridine and 1- β -D-Arabinofuranosylcytosine on the Kinetics of Repair. (Eng) Erixon, K. (Dept. Radiation Chemistry, Wallenberg Lab., Univ. Stockholm, S-10691 Stockholm, Sweden); Ahnstrom, G. *Mutat Res* 59(2): 257-271; 1979.

UV light-induced excision repair was studied in normal human fibroblasts and in fibroblasts from patients with xeroderma pigmentosum (XP). At 0 C, UV light (20 joules/m²) produced a very low frequency of strand breaks in normal cells; on subsequent incubation at 37 C, breaks formed and then disappeared in a dose-dependent fashion. Hydroxyurea (HU: 10⁻² M), 5-fluorodeoxyuridine (FUDR: 2 x 10⁻⁶ M), and 1- β -D-arabinofuranosylcytosine (araC: 10⁻⁴ M) dramatically increased the number of breaks. The effects of FUDR were reversed by subsequent incubation with 50 μ M thymidine. Essentially no breaks were induced by UV light in XP cells belonging to complementation group A (XP-A), and there was no enhancement by HU. Cells from XP variants with no reduction in pyrimidine dimer excision or unscheduled DNA synthesis reacted in a manner similar to that of normal cells. When XP variant and normal cells were incubated at 37 C for 10 min following irradiation, the number of breaks increased with UV dose and a saturation level was reached. HU or araC enhanced this response considerably. For XP-A cells, there was essentially no dose effect, either in the absence or presence of HU. (58 refs)

- 79-2672 The Effect of 8-Methoxypsoralen-Plus Ultraviolet Light on Cell-Virus Interaction:

The Transforming Infection: Effect of PUVA on the Transformation of Baby Hamster Kidney Cells by Polyoma Virus. (Eng) Morhenn, V. B. (Dept. Dermatology, Stanford Univ. Medical Center, Stanford, CA); Kaye, J. A. *J Invest Dermatol* 72(3): 138-142; 1979.

The effects of pretreatment with 8-methoxypsoralen (8-MOP) + UV light (PUVA) on the transformation of baby hamster kidney (BHK) cells by polyoma virus (Py) were studied. PUVA enhanced viral transformation, the enhancement increasing with decreasing cell survival and being max at 0.5 μ g/ml 8-MOP + 0.3 joule (J)/cm² UV light. The number of transformed colonies increased with virus concentration, and the enhancement factor due to PUVA was independent of the multiplicity of infection. The drug and light acted synergistically in enhancing viral transformation. The absolute number of transformed colonies in the PUVA-pretreated Py-infected cultures was smaller than that in control infected cultures; therefore, the enhancement of transformation was dependent on correction for the number of cells capable of growing after PUVA treatment. PUVA had no transforming effects on uninfected BHK cultures. The PUVA-pretreated, Py-infected cells were tumorigenic following sc injection (10⁶ cells) into hamsters (9/9 and 5/6 injected animals had tumors). Viral transformation was enhanced sixfold at a PUVA concentration (0.01 μ g/ml 8-MOP + 1.2 J/cm² UV) that inhibited DNA synthesis to 75% of control levels at 38 hr after treatment. (42 refs)

- 79-2673 Quantitative Studies of Radiation Transformation with the A31-11 Mouse BALB/3T3 Cell Line. (Eng) Little, J. B. (Lab. Radiobiology, Dept. Physiology, Harvard Sch. Public Health, Boston, MA 02115) *Cancer Res* 39(5): 1474-1480; 1979.

A cloned BALB/3T3 mouse embryo-derived fibroblast cell line (A31-11) was used to study morphological transformation induced by x-rays and 254-nanometer UV light. The transformation frequency increased exponentially with increasing dose from 10 to 400 rads for x-rays and 1.0 to 7.5 joules/m² for UV exposure. Split-dose x-ray exposures led to an enhancement in transformation at total doses <100 rads and a reduction at doses of 300-400 rads. The induced transformation frequency varied among serum lots and was very dependent upon the initial cell density. Spontaneous transformants were observed in 10/22 consecutive experiments; the spontaneous transformation frequency was generally about 1 to 2 x 10⁻⁵, compared with induced frequencies that ranged up to 3 x 10⁻³ for x-rays and 7.5 x 10⁻⁴ for UV exposure. Further results indicated that this cell line has several potential advantages over the mouse 10T1/2 line for studies with relatively weak in vitro carcinogens such as radiation. These include (1) a reduced overall expression time for the appearance of transformed foci (4 wk); (2) a high cloning efficiency (50%-60%); and (3) the fact that about 20 times as many viable cells may be

plated per dish for optimal results, allowing transformation frequencies as low as 10^{-5} to be measured easily. On the other hand, there was more variability in the result of experiments with the 3T3 cell line. (26 refs)

79-2679 Radiation Exposure and the Simultaneous Occurrence of Primary Hyperparathyroidism and Thyroid Nodules. (Eng) Nishiyama, R. H. (Dept. Pathology, Univ. Michigan Medical Center, Ann Arbor,

MI); Farhi, D.; Thompson, N. W. *Surg Clin North Am* 59(1): 65-75; 1979.

The role of ionizing radiation in the pathogenesis of thyroid carcinoma and hyperparathyroidism (HPT) was studied among 42 women and 11 men with concomitant thyroid disease and primary HPT. The presenting symptoms were related to HPT in 30 patients and to thyroid disease in 3; 20 were asymptomatic. The pathologic changes in the thyroid glands included nodular goiters in 33 patients, follicular carcinomas in 3, papillary carcinomas in 10, and Hashimoto's disease in 7. Thirty-four percent of the patients had been exposed to head and neck radiation an av of 29 yr prior to the detection of thyroid or parathyroid disease; radiation histories were incomplete in many cases. Of the 13 patients with thyroid carcinoma, 9 had been exposed to radiation and 4 had not. Seven of the nine irradiated thyroid carcinoma patients also had parathyroid adenomas, as did all nonirradiated patients with thyroid carcinomas. Only one patient with follicular carcinoma had a history of head and neck irradiation. The data indicate that undetermined etiologic factors other than radiation may be involved in the simultaneous appearance of HPT and thyroid carcinomas in some patients. (46 refs)

79-2680 Association of Malignancy with Rapid Growth in Early Lesions Induced by Irradiation of Rat Skin. (Eng) McGregor, J. F. (Biology and Health Physics Div., Atomic Energy Canada, Ltd., Chalk River, Ontario, Canada K0J 1J0) *J Natl Cancer Inst* 62(4): 1043-1049; 1979.

Cancerous and noncancerous epithelial lesions induced by irradiation of rat skin were studied to determine (1) the relationship of malignancy to dose, (2) the types of lesions and circumstances leading to overt malignancy, and (3) the growth rates of lesions progressing to malignancy vs those of lesions remaining benign. High doses of radiation were associated with the production of epidermal cancers, the max yield being obtained at 6,400 rads. Conversely, a peak yield of noncancerous lesions was obtained at 1,600 rads. This association between malignancy and high dose was consistent for cancers evolving from warts, cysts, and chronic ulcers. Although the proportion of warts among the induced lesions was much higher than that of the cysts or chronic ulcers (76%, 14%, and 10%, respectively), the likelihood of warts becoming cancerous was substantially lower (14%, 23%, and 21%). The combined data for all doses showed that the latency period of the epidermal cancers was significantly ($p = 0.015$) shorter than that of the benign tumors. Rapid growth rates were observed for warts, cysts, and chronic ulcers progressing to overt cancer, and these did not overlap at any point on the growth scale with rates for benign tumors. This finding suggests that the potential for malignant development had been established early in the carcinogenic process, very likely at induction. (15 refs)

- 79-2681 **Assessment of Biological Damage by Personal Neutron Dosimeters.** (Ger) Dorschel, B. (Sektion Physik, Technische Universität Dresden, Mommsenstrasse 13, DDR-8027 Dresden, E. Germany); Herforth, L. *Kernenergie* 21(12): 377-382; 1978.

The feasibility of assessing biological damage due to neutron irradiation by personal neutron dosimeters was determined. The direct calibration of detectors used as personal dosimeters is possible only if the neutron field is known. (10 refs)

- 79-2682 **Comments on Leukemia Risk from Neutrons (2 Letters to Editor).** (Eng) Jablon, S. (6813 Persimmon Tree Road, Bethesda, MD 20034); Rossi, H. H.; Mays, C. W. *Health Phys* 36(2): 205-206; 1979.

A previous estimation that a worker who received the max permissible dose of neutrons for 50 yr would have five times the naturally occurring risk of death from leukemia is stated to be an overestimation by a factor of about 5. Also, there is no convincing evidence that the limits of low-LET (linear energy transfer) radiations are conservative. In a reply, it is agreed that the estimate may be high, but that the error is <30%. Facts are also presented indicating that the notion of a dose-independent relative biological effectiveness of neutrons relative to gamma radiation must be rejected. (3 refs)

- 79-2683 **Morphological Study of the Bone Marrow in Patients Injected with ThO₂.** (Eng) Parreira, F. (Hematology Lab., Universidades de Lisboa, Hospital de Santa Maria, Lisbon 4, Portugal); Carneiro de Moura, M. *Environ Res* 18(1): 61-64; 1979.

The bone marrow morphology of 12 patients who had been injected with thorium dioxide colloid (Thorotrast) 21-39 yr earlier was studied. Eight patients had anemia, most with normal or slightly decreased mean cell Hb values. One patient had acute myeloblastic leukemia (AML), one cholangiocarcinoma. Cellularity was normal in only four patients; the degree of hypoplasia resulted in aplasia in some patients. Excluding the AML patient, all patients had an abnormal myeloid:erythroid ratio; in these patients, including those with an apparently normal cellularity, granulocytopenia was depressed. It is concluded that the pathogenesis of anemia can be explained by proliferative asthenia. There is no explanation for the lack of correlation between the myeloid:erythroid ratio and the WBC count in the peripheral blood. There was also no correlation between the degree of bone marrow hypoplasia and the duration of radiation. (no refs)

- 79-2687 **The Gastrointestinal Absorption of Plutonium and Americium in the Hamster.** (Eng) Stather, J. W. (Natl. Radiological Protection Board, Harwell, Didcot, Oxfordshire, OX11 0RQ, England); Harrison, J. D.; Rodwell, P.; David, A. J. *Phys Med Biol* 24(2): 396-407; 1979.

Plutonium-239 and americium-241 were given to adult Syrian golden hamsters in various chemical forms and by various routes, and their absorption from the gut was measured. One month after iv injection of the citrate complexes of ²³⁹Pu [400 Becquerels (Bq)] or ²⁴¹Am (100 Bq), the skeleton and liver contained >90% of the total body content of both actinides. The absorption of ²³⁹Pu from the gastrointestinal tract varied from 0.01% to 0.00003%, depending on the chemical form administered. The highest values were obtained after protracted administration of the nitrate (50 doses of 0.74 kBq, po), administration of a single dose as the citrate complex (12 kBq), or administration of ²³⁹Pu in a biologically incorporated form in hamster liver (44 kBq). Intermediate values were obtained with single doses of the mixed oxide (36 kBq) and the nitrate (9.3 kBq), the lowest value with the dioxide (75 kBq). The absorption of ²⁴¹Am from the gastrointestinal tract varied from 0.06% to 0.004%. The highest value was obtained after administration of the nitrate (35 kBq). A single dose of the citrate (33 kBq) gave intermediate values, and the dioxide (237 kBq) and liver-incorporated (37 kBq) forms gave the lowest absorption values. ²⁴¹Am was absorbed more readily than ²³⁹Pu. When these values were compared with those for other species, no large variations were observed that

could be attributed to species differences, providing some justification for extrapolation of the results to humans. On the basis of current best knowledge, the best values for the estimated absorption in human adults appear to be 0.05% for Am, 0.01% for Pu ingested in soluble form, and 0.0001% for Pu ingested as the dioxide. - 79-2688 Ingested Mineral Fibers: Elimination in Human Urine.** (Eng) Cook, P. M. (U.S. Environmental Protection Agency, Environmental Res. Lab., 6201 Congdon Blvd., Duluth, MN 55804); Olson, G. F. *Science* 204(4389): 195-198; 1979.

Sediment filtered from human urine samples was examined by transmission electron microscopy in order to determine whether asbestos or other mineral fibers might be present. The urine samples were collected from male and female Minnesota residents, all in good health. Samples from individuals who drank only unfiltered water (from Western Lake Superior) contained 310-1,170 amphibole fibers/ml, whereas those from individuals who drank only filtered water contained 13-40 fibers/ml. The urine of two men, after months of ingesting only filtered water, contained less than one-tenth the amphibole fiber concentrations found in the urine when these same men drank only unfiltered water. This indicates that the amphibole fiber concentrations are associated with the type of drinking water. The results also indicate that mineral fibers can pass through the human gastrointestinal mucosa under normal conditions of the alimentary canal. Concentrations of amphibole fibers eliminated in urine represented approx 10^{-3} of the number of fibers ingested with drinking water. This ratio seems remarkably large and may be modified by further measurements. Diurnal variations in kidney function were not accounted for, and the magnitude for intersubject variability in gastrointestinal mucosa, kidney, and other tissue permeability to the particles is unknown. To the extent that some fibers are permanently retained by the body or are eliminated by other routes, however, the urine concentrations are an underestimate of the ingested fiber absorption. - 79-2690 Pulmonary Response to Glass Fiber by Inhalation Exposure.** (Eng) Lee, K. P. (Haskell Lab. Toxicology and Industrial Medicine, E. I. du Pont de Nemours and Co., Inc., Wilmington, DE 19898); Barras,

C. E.; Griffith, F. D.; Waritz, R. S. *Lab Invest* 40(2): 123-133; 1979.

The ultrastructural details of the pulmonary response of several animal species to fiberglass exposure are described, with emphasis on a alveolar proteinosis. Male Charles River, C-D Sprague-Dawley-derived rats, male Syrian hamsters, and male albino guinea pigs were exposed to airborne glass fibers at a gravimetric concentration of 0.42 mg/liter for 6 hr/day, 5 days/wk, for 90 days. The number of dust particles $>5 \mu\text{m}$ long was $0.73 \times 10^6/\text{liter}$; the av diameter of the particles was approx $1.2 \mu\text{m}$. Most particles were approx $0.2\text{-}3.5 \mu\text{m}$ in diameter, and only 15% had a fibrous shape. Few fibers were longer than $10 \mu\text{m}$. The pulmonary response was characterized by macrophage reaction with proliferation of granular pneumocytes and alveolar proteinosis at 90 days of inhalation exposure. The light and ultrastructural alterations were similar to those of other experimental alveolar proteinosis or human alveolar proteinosis. The alveolar proteinosis disappeared at 1 yr postexposure, but focal dust cell accumulation with proliferating granular pneumocytes persisted throughout the 2-yr recovery period. No significant fibrosis or stromal changes were found in the dust-deposited areas. In hamsters and guinea pigs, most ferruginous bodies were developed from fibrous fibers but not from tiny dust particles. The tracheobronchial lymph nodes were markedly swollen and laden with dust cells. (35 refs)

- 79-2691 Glass Fiber-induced Foreign Body Granuloma.** (Ger) Lechner, W. (Dermatologische Klinik, Universität Würzburg, Josef-Schneider-Strasse 2, D-8700 Würzburg, W. Germany); Hartmann, A. A. *Hautarzt* 30(2): 100-101; 1979.

A 6-yr-old girl developed foreign body granulomas in the gluteal region, on the flexor sides of the lower legs, and in the dorsal parts of the feet. Microscopic examination of biopsy specimens revealed phagocytized glass fiber particles. The girl used to play in a shed in which fiberglass was stored. The foreign body granulomas regressed spontaneously without treatment. (5 refs)

- 79-2692 "Spontaneous" Neoplastic Transformation In Vitro: A Form of Foreign Body (Smooth Surface) Tumorigenesis.** (Eng) Boone, C. W. (Cell Biology Section, Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD 20014); Takeichi, N.; del Ande Eaton, S.; Paranjpe, M. *Science* 204(4389): 177-179; 1979.

An attempt was made to determine whether the association in vitro between the smooth surface of a tissue culture vessel and explanted sc connective tissue cells could give rise to tumors. Explants of sc connective tissue from adult BALB/c mice in plastic petri dishes were serially sub-

cultured and tested for tumorigenicity by (1) sc implantation of cells attached to plastic plates ($1 \times 5 \times 10$ mm) and (2) sc injection of cells suspended in saline. Cells grown in vitro for ≥ 18 days before being implanted while attached to a plastic plate (2.4×10^4 to 3.4×10^5 cells/plate) formed tumors in the mice after 24-79 wk. The latent period before tumor appearance correlated inversely with the time spent by the cells in tissue culture. Cells injected in saline suspension (10-100 times the above number/plate) did not form tumors until >84 days in vitro; plates alone did not induce tumor formation within >1.5 yr of implantation. The tumors arising from the plate-attached cells were transplantable without plates and, histologically, appeared to be undifferentiated sarcomas. It is well-established that smooth-surfaced foreign bodies, regardless of their chemical composition, will produce sarcomas when transplanted sc in rodents. The data from these studies, particularly the decrease in tumor latent period with time spent in tissue culture, are interpreted as indicating that a smooth surface was acting as a carcinogen first in vitro (the surface of the tissue culture dish) and then in vivo (the surface of the plastic plate). 79-2693 Hyperplastic Polyps of the Gastric Mucosa Adjacent to Gastroenterostomy Stomas. (Eng)
Stemmermann, G. N. (Dept. Pathology, Kuakini Medical Center, 347 N. Kuakini St., Honolulu, Hawaii 96817); Hayashi, T. *Am J Clin Pathol* 71(3): 341-345; 1979.

In two men (aged 58 and 80 yr) with functionally active, nonatrophic oxyntic gastric mucosa, hyperplastic polyps developed on the gastric side of Billroth II and Billroth I anastomoses. The polyp associated with the Billroth II procedure was almost circumferential, sparing only the lesser curvature. That associated with the Billroth I operation was on the anterior wall from the lesser to the greater curvature. The operations had been performed 11 and 10 yr earlier for peptic ulcers of the gastroduodenal junction. The sites of polyp formation resembled those of experimental cancers in rats with Billroth I and Billroth II anastomoses and those of human cancers occurring ≥ 20 yr after gastrojejunostomy for benign disease. This suggests that stomal carcinomas and hyperplastic polyps each result from the reflux of enteric contents into the stomach remnant. (12 refs)

VIRAL CARCINOGENESIS

- 79-2694 **tRNA-Trp as Primer for RNA-Directed DNA Polymerase Structural Determinants of Function.** (Eng) Cordell, B. (Dept. Biochemistry and Biophysics, Univ. California, San Francisco, CA 94143); Swanstrom, R.; Goodman, H. M.; Bishop, J. M. *J Biol Chem* 254(6): 1866-1874; 1979.

The specific interactions between the RNA-directed DNA polymerase of avian oncornavirus and the transfer RNA-Trp (tRNA-Trp) primer required for initiation of viral DNA synthesis in vitro were examined. Two distinct interactions, stable binding of the tRNA-Trp to the enzyme and initiation of viral DNA synthesis by the enzyme with tRNA-Trp as primer, were characterized as to the structure of tRNA-Trp required. Different structural features of the tRNA-Trp were necessary for each type of interaction. The entire primary structure and native conformation of tRNA-Trp were both required for binding to reverse transcriptase. Fragments of tRNA-Trp and intact tRNA-Trp in an altered conformation could not be bound by the enzyme using an assay that detects high-affinity binding between reverse transcriptase and native tRNA-Trp. In contrast, fragments of the tRNA-Trp molecule were able to serve as primers for viral DNA synthesis with normal efficiency, compared with intact tRNA-Trp. The fragments that initiate transcription must contain a minimum specific nucleotide sequence that extends from the 3' terminus of tRNA-Trp through 27 residues of the molecule. This portion of the tRNA-Trp molecule may be a major structural determinant of specificity in initiation. (32 refs)

- 79-2695 **Transformation-associated Cell Surface Antigens in Virus and Chemically Transformed Avian Cells.** (Eng) Bauer, H. (Fachbereich Humanmedizin, Institut für Virologie der Justus-Liebig-Universität Giessen, Frankfurter Strasse 107, D-6300 Giessen-Lahn, W. Germany); Ignjatovic, J.; Rubsamen, H.; Hayami, M. *Med Microbiol Immunol (Berl)* 164(1/3): 197-205; 1977.

The expression of cell-surface antigens after avian sarcoma virus (ASV) and avian leukosis virus (ALV) infection was reexamined using Japanese quail as effector and target cell donors. Cell-surface antigens were assayed by a cell-mediated cytotoxicity (CMC) test in which spleen cells from tumor-bearing or virus-immunized animals were reacted with in vitro grown target cells. Untransformed ALV-infected quail embryo cells (QEC) were killed according to a subgroup-specific antigenic pattern that was probably due to the subgroup (type)-specific determinant of gp85 expressed at the cell surface. ASV-transformed cells contained an additional antigen that did not seem to

be related to virus envelope glycoproteins because it was also demonstrable in QR(-) cells, an established quail cell line transformed by the Bryan high-titer strain of ASV that produces noninfectious (gp85-negative) particles. Virus-transformed cells shared surface antigens with chemically transformed cells from the same species. A weak cross-reaction between virus-transformed and primary embryonic cells was also found. Two-thirds of the spleens from tumor-bearing animals exerted a measurable cytotoxic effect, and the degree of cytotoxicity in some tests reached 80%. Preliminary data suggested that antibody-dependent (Fc receptor-bearing) cells are involved in this reaction. When virus-free cell extracts were prepared by KCl or nonionic detergent extraction and tested for their capacity to block CMC against individual target cells, four different antigens could be distinguished. One of these antigens was a subgroup-specific determinant of gp85 that was expressed in all productively infected or transformed cells. In the CMC test, the group-specific determinant was accessible only in cells transformed by nondefective ASV. An antigen, probably embryonic, was found in both chemically and virus-transformed cells and also in some untransformed embryo cells at low passage. Virus-transformed cells also expressed an antigen (transformation-specific antigen) that was found at the surface of or in extracts of chemically transformed or productively infected, untransformed cells. - 79-2697 **Genome of Avian Myelocytomatosis Virus MC29: Analysis by Heteroduplex Mapping.** (Eng) Hu, S. S. (Dept. Microbiology, Univ. Southern California, 2011 Zonal Ave., Los Angeles, CA 90033); Lai, M. M.; Vogt, P. K. *Proc Natl Acad Sci USA* 76(3): 1265-1268; 1979.

The genome of avian myelocytomatosis virus MC29 was compared with that of the Prague strain of Rous sarcoma virus subgroup C (RSV PR-C) by heteroduplex mapping analysis using an electron microscope. The virion RNA of MC29 was hybridized to full-length DNA of RSV PR-C. The results showed that MC29-specific sequences for which there are no homologous counterparts in the RSV genome make up a contiguous stretch of RNA about 1.8 kilobases

long. These sequences are located approx in the middle of the genome, replacing the 3' half of the *gag* gene, the entire *pol* gene, and the 5' portion of the *env* gene, which are absent from MC29. This MC29-specific genetic substitution may contain information responsible for the leukemogenic transformation of the host cell. (26 refs)

- 79-2698 **Response of Hemopoietic Cells to Avian Acute Leukemia Viruses: Effects on the Differentiation of the Target Cells.** (Eng) Gazzolo, L. (Unite de Virologie, Place Joseph Renaut, 69008 Lyon, France); Moscovici, C.; Moscovici, M. G.; Samarut, J. *Cell* 16(3): 627-638; 1979.

An attempt was made to determine whether avian leukemia viruses (ALV's) interact with myeloid cells at one specific stage or at several stages of differentiation. Chicken bone marrow cells were infected with three ALV's, avian myeloblastosis virus (AMV), myelocytomatosis virus strain MC29, and Mill Hill 2 virus (MH2), and then cultured in agar in the presence of conditioned medium. Under these conditions, very few cells served as target cells for the three ALV's. Density gradient separation showed that ALV target cells were found primarily in the light density fractions and might be represented by cells committed to the mononuclear phagocyte pathway. Separation of bone marrow cells on the basis of their sedimentation velocity at unit gravity suggested that MC29 and AMV did not share the same target cells. In addition, analysis of surface receptors and functional markers characteristic of macrophages (Fc and complement receptors, phagocytosis, and immune phagocytosis) indicated that the ALV-transformed cells were blocked during differentiation. These results indicate that the transforming ability of ALV's interferes with the differentiation of their target cells. (35 refs)

- 79-2699 **Fractionation of Two Protein Kinases from Avian Myeloblastosis Virus and Characterization of the Protein Kinase Activity Preferring Basic Phosphoacceptor Proteins.** (Eng) Rosok, M. J. (Dept. Chemistry, Univ. Montana, Missoula, MT 59812); Watson, K. F. *J Virol* 29(3): 872-880; 1979.

Two protein kinase (PK) activities were fractionated from purified virions of avian myeloblastosis virus. The distinguishing characteristics of these two PK's included (1) their binding properties during purification by ion-exchange chromatography, (2) their estimated mol wt, and (3) their phosphoacceptor protein specificities. The PK that bound to the anion exchanger 2-(diethylamino)ethanol-cellulose (pH 7.2) had an estimated mol wt of 60,000-64,000 and preferred basic phosphoacceptor proteins. The PK that bound to the cation exchanger phosphocellulose (pH 7.2) had an estimated mol wt of 42,000 to 46,000 and preferred acidic phosphoacceptor proteins. The PK prefer-

ring basic phosphoacceptor proteins was further purified and characterized. Optimal transfer of phosphate catalyzed by this enzyme required a divalent metal ion, a sulfhydryl-reducing agent, and ATP as phosphate donor. Guanosine triphosphate was not an effective phosphate donor at concentrations comparable to ATP; and the cyclic nucleotides cyclic AMP and cyclic guanosine monophosphate neither stimulated nor inhibited protein phosphorylation by the PK. The specificity of the enzyme for basic phosphoacceptor proteins extended to proteins from avian myeloblastosis virus, in that the neutral to basic virion proteins p12, p19, and p27 served as phosphate acceptors. In addition, the PK also appeared to phosphorylate itself. The possibility that this virion-associated PK could disrupt normal cellular function is discussed. (30 refs)

- 79-2700 **Restitution of Fibroblast-transforming Ability in *src* Deletion Mutants of Avian Sarcoma Virus During Animal Passage.** (Eng) Vigne, R. (Dept. Microbiology, Univ. Southern California Sch. Medicine, 2011 Zonal Ave., Los Angeles, CA 90033); Breitman, M. L.; Moscovici, C.; Vogt, P. K. *Virology* 93(2): 413-426; 1979.

Evidence for the hypothesis that partial *src* deletion mutants can reacquire sarcomagenic properties during animal passage, probably by recombining with the *src*-related sequences of normal cells, is provided. The Schmidt-Ruppin strain of Rous sarcoma virus subgroup D (SR-D) gives rise to transformation-defective (*td*) mutants that have lost either all or almost all of the *src* gene (standard *td* or *std* viruses) or have only a partial deletion of *src*. These partial deletion mutants, designated *ptd* viruses, contain genomic RNA that is slightly larger than that of the *std* isolates, and heteroduplex analyses suggest that *ptd* viruses retain approx 25% of *src* from the 5' end of that gene. Several *ptd* isolates of SR-D were injected into newly hatched chickens and, after prolonged latent periods, caused sarcomas in about 30% of the birds. The tumors occurred in internal organs away from the site of injection. Infectious sarcoma viruses isolated from these growths have the envelope markers of subgroup D, are nondefective for replication, and induce a transformation in vitro that is morphologically distinct from that of SR-D. Electrophoresis of 35S genomic RNA from these recovered sarcoma viruses showed it to be of the size characteristic for nondefective sarcoma viruses. Fingerprint analysis of ³²P-labeled RNA from one of the new sarcoma viruses detected all oligonucleotides present in *ptd* viruses, the *src*-specific oligonucleotides of SR-D, and one new oligonucleotide not present in SR-D. This new RNase T₁-resistant oligonucleotide and the *src*-specific oligonucleotides identical to those of SR-D map close to the 3' end in the genome of the recovered sarcoma virus, which is the position expected for the *src* gene. These studies suggest that recovered avian sarcoma viruses have

acquired cellular sequences that are closely related in structure and function to the viral *src* gene. (35 refs)

- 79-2701 Relationship Between Changes in the Calcium Dependent Regulatory Protein and Adenylate Cyclase During Viral Transformation. (Eng) LaPorte, D. C. (Dept. Pharmacology, Univ. Washington, Seattle, WA 98195); Gidwitz, S.; Weber, M. J.; Storm, D. R. *Biochem Biophys Res Commun* 86(4): 1169-1177; 1979.

Because of previous observations that the levels of calcium-dependent regulatory protein (CDR) in transformed chicken embryo fibroblasts (CEF) are higher in soluble and membrane fractions compared with untransformed cells, the kinetics for changes in CDR levels, hexose transport, and adenylate cyclase (AC) activity during transformation were examined using a temperature-sensitive mutant of Rous sarcoma virus (tsNY68). Decreases in AC activity and increased hexose transport accompanying transformation occurred with half-lives of approx 7-8 hr. Increases in CDR occurred much slower, with a half-life of 17 hr. Thus, the increase in CDR levels accompanying the transformation of CEF by RSV is a late event that occurs after the decrease in AC activity and increased hexose transport. Therefore, the decline in AC activity cannot be due to changes in the amount of CDR. In addition, differences in AC calcium sensitivity that were found in normal and transformed membranes were not due to changes in the amount of CDR, since these membrane preparations contained comparable levels of CDR. It seems likely that Ca^{2+} (CDR) cannot modulate AC activity in transformed membranes because of alterations in the AC system or membrane environment. (11 refs)

- 79-2702 Detection of the Viral Sarcoma Gene Product in Cells Infected with Various Strains of Avian Sarcoma Virus and of a Related Protein in Uninfected Chicken Cells. (Eng) Brugge, J. S. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO 80262); Collett, M. S.; Siddiqui, A.; Marczyńska, B.; Deinhardt, F.; Erikson, R. L. *J Virol* 29(3): 1196-1203; 1979.

Sera from marmosets bearing tumors induced by the Bryan or Schmidt-Ruppin (SR) strains of avian sarcoma virus (ASV), TBM sera, were used to screen cells transformed by four ASV strains for the presence of the polypeptide product of the *src* gene of SR-ASV, a 60,000-dalton phosphoprotein designated pp60src. TBM sera contained antibody that precipitated the transforming gene product from cells transformed by the SR, Bryan, Prague, or Bratislava strains of ASV. In contrast, rabbits bearing tumors induced by the Bratislava or Bryan strains or hamsters with SR-ASV-induced tumors did not produce antibody to pp60src from any ASV strain. The immune response to pp60src was found to be dependent on the

species of tumor-bearing host and, in the case of rabbits, also on the virus strain used for tumor induction. The immunological basis for these differences in response to pp60src is not known. The 60,000-dalton polypeptides immunoprecipitated with TBM serum from cells transformed by each of the four virus strains were phosphoproteins. One-dimensional peptide mapping by limited proteolysis revealed that the pp60src proteins were structurally very similar, but not identical. Furthermore, all the viral pp60src proteins had an associated phosphotransferase activity. In addition to detecting the viral *src* proteins, TBM serum was able to immunoprecipitate an antigenically related protein from normal uninfected avian cells. These data suggest that the mechanism of ASV-induced sarcomagenesis by all four virus strains may be mediated by protein phosphorylation. However, differences in the nature of cellular transformation by the various ASV strains may be reflected in the slight variations in the primary structure or secondary protein modification of the respective pp60src proteins. These variations may result in slight changes in the specificity of phosphorylation of cellular target polypeptides phosphorylated by the transforming proteins. (16 refs)

- 79-2703 An Avian Oncovirus Mutant Deficient in Genomic RNA: Characterization of the Packaged RNA as Cellular Messenger RNA. (Eng) Gallis, B. (Dept. Biochemistry, Univ. Washington, Seattle, WA 98195); Linial, M.; Eisenman, R. *Virology* 94(1): 146-161; 1979.

The RNA from SE 21Q1B virions was analyzed by in vitro translation and by characterization of the in vitro-synthesized proteins by physical, chemical, and immunological techniques. SE 21Q1b is a noninfectious recombinant avian oncovirus [Prague strain of Rous sarcoma virus subgroup C (PR-RSV-C) x Rous-associated virus type O] continuously produced by a line of transformed quail cells. Virions of SE 21Q1b contain 1%-2% of the normal amounts of RSV-specific RNA found in PR-RSV-C virions and substantial quantities of heterogeneously sedimenting nonviral RNA. RNA extracted from purified virions of SE 21Q1b is as efficient a template for amino acid incorporation in a messenger RNA (mRNA)-dependent reticulocyte lysate as oligo(dT)-cellulose-purified cellular mRNA. Virion RNA from SE 21Q1b serves as a template in vitro for a small amount of the precursor to the internal structural proteins (*gag* proteins). Unlike RNA from other avian oncoviruses, SE 21Q1b RNA makes, in addition, several proteins whose sizes on sodium dodecyl sulfate-polyacrylamide gels resemble those of a number of uninfected quail fibroblast proteins. The proteins range in size from 15,000 to 22,000 daltons. Immunoprecipitation of proteins synthesized in vitro from SE 21Q1b virion RNA with antisera against the *gag*, *pol*, and *env* gene products shows that this RNA serves as a template for one viral gene product, the recombinant

gag gene precursor of 72,000 daltons (Δ Pr76). Addition of lysed virus to proteins made in vitro from PR-C RNA or RNA from PR-E-95c, a recombinant whose *gag* gene structure is similar to that of PR-E-21Q1b, results in the cleavage of *gag* protein precursors into several of the internal structural proteins. On the other hand, products of translation of PR-E-21Q1b RNA are not detectably cleaved into the internal structural proteins, suggesting that a very low amount of PR-E-21Q1b translation products are *gag*-related. A 37,000-dalton protein constitutes about 15% of the total protein synthesized from SE21Q1b RNA. Data from serological and peptide mapping studies indicate that this protein is unrelated to the virion *gag*, *pol*, or *env* proteins. However, the major tryptic peptide of this protein appears to be identical to the major peptide of a prominent quail cell protein having the same apparent mol wt as the in vitro translation product. Thus, several lines of evidence suggest that SE21Q1b virions contain substantial amounts of functional cellular mRNA's. (59 refs)

- 79-2704 **Recombinant Avian Oncoviruses. II. Alterations in the *gag* Proteins and Evidence for Intragenic Recombination.** (Eng) Shaikh, R. (Dept. Pathology, Harvard Medical Sch., Boston, MA 02115); Linial, M.; Brown, S.; Sen, A.; Eisenman, R. *Virology* 92(2): 463-481; 1979.

The internal structural (*gag*) proteins of recombinant avian oncoviruses selected for the *env* gene of Rous-associated virus-O [(RAV-O) an endogenous chicken virus] and the *src* gene for the Prague C strain of Rous sarcoma virus (PR-RSV-C) were examined. Eight of ten clones of recombinant viruses synthesized altered *gag* proteins. Therefore the proteins of a representative recombinant clone, PR-E-95c, were examined in detail by gel electrophoresis and tryptic peptide mapping, to distinguish between the *gag* proteins of the two parental viruses and to determine from which virus the proteins of the recombinant virus were derived. PR-E95c virions contained p27, an electrophoretically distinguishable variant of p27 that is found in isolates of RAV-O. This recombinant virus also contained p12/15, which is electrophoretically indistinguishable from the p12/15 of both of the parental viruses. However, tryptic peptide analysis of p15 indicated that PR-E-95c had inherited PR-RSV-C-specific p15 sequences. These observations suggested that at least one cross-over had occurred between p15 and p27 in PR-E-95c. The PR-E-95c proteins and those of the parental viruses differed markedly in that the recombinant lacked polypeptides migrating in the position of p19 and contained two novel polypeptides termed p19 α (mol wt 20,000) and p19 β (mol wt 15,000). Both polypeptides were phosphorylated and shared antigenic determinants and some tryptic peptides with parental p19. As determined by peptide analysis and radioimmunoassay, these p19-related proteins contained information from both parental viruses, suggesting that PR-E-95c had another cross-over within p19. The altered p19 proteins

bound to viral RNA specifically and were associated with genomic RNA in the virion. Neither the stability nor the specific infectivity of the recombinant viruses appeared to be significantly affected by the altered proteins. (43 refs)

- 79-2705 **Comparison of the Small RNAs of Polymerase-deficient and Polymerase-positive Rous Sarcoma Virus and Another Species of Avian Retrovirus.** (Eng) Sawyer, R. C. (Cancer Res. Labs., Woodhaven, NY 11421); Hanafusa, H. *J Virol* 29(3): 863-971; 1979.

The role of the polymerase reverse transcriptase molecule in the selection of small RNA's for packaging was studied using chicken cells transformed by the polymerase-positive Bryan strain of Rous sarcoma virus (BH-RSV) and the polymerase-negative strain (BH-RSV α). The cultures were labeled with phosphorus-32, and the viral RNA's were purified and separated by two-dimensional polyacrylamide gel electrophoresis. The gel pattern of small RNA's of BH-RSV represented a specific subset of host cell small RNA's and was indistinguishable from those of the nondefective Schmidt-Ruppin strain of RSV and two different leukemia viruses, Rous-associated virus 1 (RAV-1) and RAV-2. Virions of BH-RSV α incorporated an unselected population of small RNA's identical to total chicken cell small RNA. Virions of reticuloendotheliosis virus, which contains a reverse transcriptase unrelated to that of the avian leukemia and sarcoma viruses, contained a distinctly different population of small RNA's although both the avian leukemia and sarcoma and the reticuloendotheliosis viruses were grown in chicken cells. Since the primer for avian leukemia and sarcoma virus RNA-dependent DNA synthesis is a host cell transfer RNA, the differences in reverse transcriptase small RNA selection may help explain the failure of different species of retroviruses to complement for the reverse transcriptase. (43 refs)

- 79-2706 **Purification and Partial Characterization of a Protein Kinase from the Prague-C Strain of Rous Sarcoma Virus.** (Eng) Hizi, A. (Dept. Cell Biology and Histology, Tel Aviv Univ. Sch. Medicine, Tel Aviv, Israel); Wunderli, W.; Joklik, W. K. *Virology* 93(1): 146-158; 1979.

A protein kinase was purified from Rous sarcoma virus strain Prague-C by chromatography on 2-(diethylamino)ethanol-cellulose and phosphocellulose, followed by glycerol density gradient centrifugation. The purified enzyme had a sedimentation coefficient of about 2.5S, corresponding to a mol wt of about 11,000. The sedimentation coefficient of the enzyme in virus lysates was 3.9S, corresponding to a mol wt of about 45,000. Comparison of the enzyme's chymotryptic and CNBr cleavage products with those of p15, p12, and p10 showed that it

was not identical with any of these polypeptides. The enzyme required divalent metal ions for activity, Mg^{2+} being preferred to Mn^{2+} . It did not depend on cyclic nucleotides for activity. Its K_m for ATP and guanosine triphosphate (GTP) were 40 and 870 μM respectively, but the V_{max} at saturating triphosphate concentrations was 5 x higher with GTP than with ATP. The most efficient exogenous phosphate acceptor was casein, followed by phosphatidylserine and arginine-rich histone. The most efficient phosphate acceptors in virus lysates were two small polypeptides that were probably the enzyme subunit itself and p12, followed by p19 and unidentified >50,000-mol-wt proteins that were probably traces of host cell polypeptides in the virus envelope. In virus lysates that had been heated for 2 min at 90 C and supplemented with purified kinase, the most active phosphate acceptor was an unidentified protein with a mol wt of about 38,000. (28 refs)

- 79-2707 Infectivity of Proviral DNA from Avian Sarcoma Virus-transformed Mammalian Cells.** (Eng) Catala, F. (Institut Curie, Faculte des Sciences, Orsay, France); Vigier, P. *J Virol* 29(3): 833-839; 1979.

The number of Rous viral genomes in the cellular DNA of two subclones (RS2/3, RS2/6) derived from the same clone of hamster BHK-21 cells transformed by Rous sarcoma virus (RSV) was determined by hybridization with viral complementary DNA, and the capacity of the cellular DNA to infect (transfect) chicken embryo fibroblasts (CEF) was compared before and after shearing this DNA to the proviral genome size (6×10^6 to 7×10^6 daltons). The two subclones differed widely in their capacity to give rise to virus (inducibility) after fusion with CEF and in their level of viral protein expression. Subclone RS2/3 was the most inducible and expressed appreciable levels of viral proteins; no proteins were detected in subclone RS2/6. Cells of both subclones contained a single copy of RSV DNA and yielded infectious DNA. However, whereas transfection of CEF was successful with both unsheared ($\geq 18 \times 10^6$ daltons) and sheared DNA from subclone RS2/3, transfection with DNA from subclone RS2/6 succeeded only with sheared DNA. The infectivity of the sheared DNA approximated that of sheared or unsheared RS2/3 DNA. The lack of infectivity of unsheared RS2/6 DNA may be explained by a hypothesis previously proposed to account for the lack of infectivity of DNA from certain chicken cells producing spontaneously low amounts of Rous-associated virus-O (RAV-O) and resistant to exogenous RAV-O infection; that is, that the viral genome (proviral DNA) is linked to a *cis*-acting control element that blocks its expression. In RS2/6 cells, this linkage might originate from translocation of cellular DNA containing the single proviral copy. (33 refs)

- 79-2708 Formation of Rous Associated Virus-60: Origin of the Polymerase Gene.** (Eng) Sawyer,

R. C. (Cancer Res. Labs., Woodhaven, NY 11421); Rettenmier, C. W.; Hanafusa, H. *J Virol* 29(3): 856-862; 1979.

The DNA of normal chicken embryos contains sequences related to the avian leukosis-sarcoma viruses whose RNA-dependent DNA polymerase is encoded by as the *pol* gene. The nature of the endogenous virus *pol* gene in chicken cells was investigated by testing its ability to participate in genetic recombination. Rous-associated virus-60 (RAV-60) recombinant viruses isolated after infection of chicken cells with strains tsLA33PR-B or tsNY21SR-A, both of which produce a temperature-sensitive DNA polymerase, also possessed the temperature-sensitive lesion. These results are consistent with the hypothesis that the endogenous viral information used for the generation of RAV-60 is deficient in at least part of the *pol* gene and that the defect includes that portion represented by the lesions in NY21 and LA337. The frequency of polymerase-negative BH-Rous sarcoma virus α formation was not affected by the levels of endogenous viral expression, which suggests that the α defect is not derived from the endogenous *pol* gene. (47 refs)

- 79-2709 Messenger Activity of Virion RNA for Avian Leukosis Viral Envelope Glycoprotein.** (Eng) Stacey, D. W. (Rockefeller Univ., New York, NY 10021) *J Virol* 29(3): 949-956; 1979.

The RNA from particles of Rous-associated virus type 2 (RAV-2) was analyzed by an intracellular assay for viral envelope glycoprotein (*env*) messenger. RAV-2 RNA was microinjected into cells infected by the *env*-deficient Bryan strain of Rous sarcoma virus [(RSV(-) cells)]. Only when the injected RNA could be translated by the recipient cells to produce viral envelope glycoprotein was the *env* deficiency of the RSV(-) cells complemented, enabling them to release focus-forming units (FFU). The 21S RNA from the RAV-2 virus particle promoted the release of numerous FFU from RSV(-) cells, but the major 35S virion RNA species was inactive. The *env* messenger activity sedimented as a sharp peak with high specific activity. RNase T1-generated fragments of virion 35S RNA were unable to promote the release of infectious virus from RSV(-) cells, which suggested that the active molecule was *env* messenger encapsulated by the virus particle directly from the cytoplasm of infected cells. Approx 95% of the *env* messenger was associated with the virion high-mol-wt RNA complex. The temperature required to dissociate *env* messenger from this complex was the same as that required to disrupt the complex itself. Virion high-mol-wt RNA that was associated with *env* messenger sedimented slightly more rapidly than the bulk virion RNA; this was the strongest evidence that the 21S messenger had been encapsulated directly from the infected cells. These data, along with the prolonged expression of *env* messenger after injection into RSV(-) cells, raise the possibility that virus-encapsulated *env* messenger can become expressed within subsequently infected cells. (33 refs)

- 79-2710 Production of Avian Oncoviral Subgroups after Multiple Infection.** (Eng) Khoury, A. T. (Wistar Inst. Anatomy and Biology, Philadelphia, PA 19104); Hanafusa, H.; Namy, C. A. *J Virol* 29(3): 926-937; 1979.

An attempt was made to determine if there is a limit to the number of different proviral DNA's that can be expressed by a single chicken embryo fibroblast. Fibroblasts were infected with one to three subgroups of Rous-associated virus, which is a nontransforming avian oncovirus, then superinfected with a transforming virus, Rous sarcoma virus, of a different subgroup. The subgroups of viruses released by the resulting clones were analyzed. When two viral subgroups were used for preinfection, all the resulting clones produced transforming virus particles having the subgroup of the superinfecting virus, and most clones produced transforming virus particles of all the infecting viral subgroups. However, when cells were preinfected with three viral subgroups, many of the resulting clones did not produce transforming virus particles having the subgroup of the superinfecting virus, and only 1/23 clones produced transforming particles of all the infecting viral subgroups. DNA annealing experiments showed that cells infected with three or four viral subgroups had an additional 8-20 copies of proviral DNA per cell. Finally, most clones resulting from cells simultaneously infected with three or four viral subgroups were able to produce virus of all infecting subgroups. It appears that the number of exogenous oncoviral *env* genes that can be expressed by a single cell is limited and in the range of 4 to 8-20 per cell. (24 refs)

- 79-2711 RNA-directed DNA Polymerase from Particles Released by Normal Goose Cells.** (Eng) Bauer, G. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706); Temin, H. M. *J Virol* 29(3): 1006-1013; 1979.

Cultured goose embryo cells released particle-associated RNA-directed DNA polymerase and RNase H activities that required the presence of Nonidet P-40 for detection. The particles were not infectious and did not have endogenous DNA synthesis. The goose particle DNA polymerase was related to the DNA polymerase of spleen necrosis virus with respect to size, and it was inhibited by IgG's directed against spleen necrosis virus DNA polymerase. However, goose cell DNA did not contain endogenous reticuloendotheliosis virus nucleotide sequences. (16 refs)

- 79-2712 Transformation by Reticuloendotheliosis Virus: Development of a Focus Assay and Isolation of a Nontransforming Virus.** (Eng) Hoelzer, J. D. (Dept. Microbiology, Univ. Texas at Austin, Austin, TX 78712); Franklin, R. B.; Bose, H. R. *Virology* 93(1): 20-30; 1979.

A focus assay for quantitating in vitro transformation by oncogenic reticuloendotheliosis virus (REV) was developed in Japanese quail embryo fibroblast cultures. The titer of the transforming virus detected in the in vitro focus-forming (FF) assay correlated with the development of reticuloendotheliosis in chickens. The titration pattern of REV FF appeared to follow two-hit kinetics. A non-transforming virus, designated REV-associated virus (REV-A), was present in REV stocks in 100- to 1000-fold excess over the transforming virus. REV-A induced an initial cytopathic effect in chick and quail embryo fibroblast cultures; the surviving cells continue to divide, leading to the development of a persistently infected culture. The persistently infected cultures were morphologically indistinguishable from uninfected avian fibroblast cultures. REV-A interfered with superinfection by the oncogenic virus. The addition of REV-A to oncogenic preparations of REV increased FF and changed the titration pattern from two-hit to one-hit kinetics, indicating that REV is defective. The identification of this defect may help in determining the specific viral products responsible for leukemogenic transformation. (42 refs)

- 79-2713 Transcription of the Marek's Disease Virus Genome in a Nonproductive Chicken Lymphoblastoid Cell Line.** (Eng) Silver, S. (Lab. Molecular Virology, Life Sciences, Inc., St. Petersburg, FL 33710); Tanaka, A.; Nonoyama, M. *Virology* 93(1): 127-133; 1979.

Transcription of the Marek's disease virus (MDV) genome in virus-nonproducing MKT-1 cells, a lymphoblastoid cell line derived from a Marek's disease tumor, was studied by analyzing the hybridization kinetics of ³H-labeled MDV DNA with unlabeled RNA extracted from whole cells or from polyribosomes. From 12% to 14% of the viral DNA template was transcribed, and only a portion (60%-70%) of the viral-specific RNA sequences found in whole cells could be detected in the polyribosomal fraction. Treatment of MKT-1 cells with 5'-iododeoxyuridine (IUdR) induced transcription of the viral genome, so that 42% of the MDV RNA template was transcribed. This represents nearly the same degree of transcription as in chicken embryo fibroblasts productively infected with MDV. Viral antigens were also produced following IUdR induction, but viral DNA replication remained restricted. Only 60%-70% of the viral-specific RNA sequences in whole cells of IUdR-treated MKT-1 cells were found in the polyribosomal fraction. The data suggest the existence within MKT-1 cells of a posttranscriptional control mechanism that selectively excludes certain RNA transcripts from stable association with the polyribosomes and that may be responsible, in part, for the repressed expression of viral genetic information in the cells. (20 refs)

- 79-2714 Integration and Expression of Mouse Mammary Tumor Virus Genes in Mice Strains Ex-**

hibiting High and Low Tumor Incidence (Meeting Abstract). (Eng) Groner, B. (Swiss Inst. Experimental Cancer Res., Chemin des Boveresses, CH-1066 Epalinges/Lausanne, Switzerland); Hynes, N. E. *Hoppe Seylers Z Physiol Chem* 360(3): 271; 1979 (no refs)

79-2715 Autogenous Antibodies Against the Murine Mammary Tumor Virus in Strains of Mice with Low Incidences of Mammary Tumors. (Eng) Michalides, R. (Div. Virology, Antoni van Leeuwenhoekhuis, Netherlands Cancer Inst., Plesmanlaan 121, Amsterdam, Netherlands); Wagenaar, E.; Nüsse, R. *J Natl Cancer Inst* 62(4): 935-941; 1979.

A radioimmunoprecipitation assay for murine mammary tumor virus (MuMTV) was used to detect naturally occurring antibodies against MuMTV in three groups of highly inbred mouse strains. (1) Strains GR and C3H have high incidences of mammary tumors. Antibodies against MuMTV were detected in the sera of females of these strains at early ages. (2) Strains C3Hf, RIII, and BALB/c have low incidences of mammary tumor with an intermediate MuMTV expression. Some females of these strains developed antibodies against MuMTV. Hormone treatment (estrogen, progesterone, and prolactin) increased the proportion of mice carrying antibodies against MuMTV. (3) Strains O20, C57BL, and GR-*Mtv*⁻ are MuMTV-free. No antibodies against MuMTV were detected in the sera of these mice. Antibodies were detected, however, after hormone treatment. The presence of a natural humoral immunity toward MuMTV appeared to be related to the expression of MuMTV in the various mouse strains. (27 refs)

79-2716 In Vitro Selection of High-infectious, Leukemogenic Virus from Low-infectious, Non-leukemogenic Type C Virus from a Malignant ST/a Mouse Cell Line. (Eng) Willumsen, B. M. (Sidney Farber Cancer Inst., Boston, MA 02115) *J Virol* 29(3): 1213-1220; 1979.

Low-infectious, nontransforming, C-type virus was isolated from an in vitro spontaneously transformed ST/a mouse cell line, ST-L1. The virus released by the ST-L1 cells was NB-tropic and XC-. It gave rise to very small peroxidase antibody plaques (PAP) in cultures that initially were nonproducing. Sodium dodecyl sulfate (SDS)-polyacrylamide gels of the structural proteins of the ST-L1 virus showed an envelope glycoprotein with an apparent mass of 65,000 daltons (65K). SC-1, BALB/3T3, and NIH/3T3 mouse cells could be productively infected with cell-free supernatants from the ST-L1 cell line; however, virus was detected in supernatant fluids only after two to four subcultures of the infected cells. The virus thus produced was XC+ and a large plaque former. The virus released from infected SC-1 cells was N-tropic, whereas the

viruses from infected NIH/3T3 and BALB/3T3 cells were NB-tropic. The structural proteins of the N- and NB-tropic viruses could be distinguished on SDS polyacrylamide gels, the major dissimilarity being a difference in the mobility of the p30. All these viruses had an envelope glycoprotein with an apparent mol wt of 70K. The infectivity of the viruses, measured as PAP per nanogram of p30, was 30- to 60-fold lower for the virus released from the ST-L1 cell line than that of the viruses released after passage in SC-1, NIH/3T3, and BALB/3T3 cells. None of the viruses could infect rabbit or mink cells. Inoculation of the viruses into newborn mice showed that the ST-L1 virus was nonleukemogenic, whereas the NB-tropic virus selected from this virus after passage in BALB/3T3 or NIH/3T3 cells was highly leukemogenic. Viruses isolated from leukemic animals were indistinguishable with respect to host range and protein mobilities in SDS gels from the infecting viruses. Although the SC-1-selected virus was highly infectious in vitro, it was only weakly, if at all, leukemogenic. (33 refs)

79-2717 Differential Distribution of Mouse Mammary Tumor Virus-related Sequences in the DNA's of Rats. (Eng) Drohan, W. (Lab. Viral Carcinogenesis, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014); Schlom, J. *J Natl Cancer Inst* 62(5): 1279-1286; 1979.

An attempt was made to determine if mouse mammary tumor virus (MuMTV)-related proviral sequences are present in the DNA of the laboratory rat (*Rattus norvegicus*). Radioactively labeled MuMTV 60S-70S RNA, obtained from virions grown in both murine and feline cells, was employed in molecular hybridization experiments to detect the MuMTV-related sequences. With the use of relaxed conditions of hybridization and assay for RNA-DNA duplexes, all strains of laboratory rats and feral rats examined were shown to possess endogenous MuMTV-related DNA sequences in the low repetitive range. These sequences were related to approx 20% of the MuMTV genome and exhibited a melting temperature (T_m) approx 5 C lower than MuMTV-specific proviral sequences in murine (*Mus musculus*) DNA's. Certain colonies of F344 (Fischer) rats contained animals whose DNA's possessed additional MuMTV-related sequences. These sequences were related to the non-germline-transmitted, tumor-associated (TA) sequences of the highly oncogenic MuMTV(C3H). They were found in the DNA of some F344 rats and a cloned established F344 rat embryo cell line at a frequency of approx one copy per haploid genome, and they exhibited a T_m 9 C lower than that of hybrid duplexes formed between radioactive MuMTV TA-sequence RNA and C3H mouse mammary tumor DNA. The DNA's of rats, therefore, contained two sets of sequences that were related to sequences of the MuMTV genome: one set was germline-transmitted, whereas the

other set appeared to be transmitted in some rats via a non-germ line or infectious process. (23 refs)

- 79-2718 **Cell-Free Synthesis of Mouse Mammary Tumor Virus Pr77 from Virion and Intracellular mRNA.** (Eng) Dahl, H. H. (Section Medical Enzymology and Molecular Biology, Univ. Amsterdam, Amsterdam, Netherlands); Dickson, C. *J Virol* 29(3): 1131-1141; 1979.

Mouse mammary tumor virus (MuMTV) was purified from two cell lines (GR and Mm5MT/c1), and the genomic RNA was isolated and translated in vitro in cell-free systems derived from mouse L cells and rabbit reticulocytes. The major translation product in both systems was a protein with a mol wt of 77,000 daltons (77K). Several other products were also detected, 110K protein and small amounts of a 160K protein. All three polypeptides were specifically immunoprecipitated by antiserum raised against the major core protein of MuMTV (p27), but they were not precipitated by antiserum against the virion glycoprotein gp52. Analysis of the in vitro products by tryptic peptide mapping established their relationship to the virion nonglycosylated structural proteins. The 77K-dalton polypeptide was found to be similar, if not identical, to an analogous precursor isolated from MuMTV-producing cells. Peptide mapping of the 110K protein showed that it contains all of the methionine-labeled peptides found in the 77K protein plus some additional peptides. It is concluded that the products synthesized in vitro from genomic MuMTV RNA are related to the nonglycosylated virion structural proteins. Polyadenylic acid-containing RNA from MuMTV-producing cells also directed the synthesis of the 77K polypeptide in the L-cell system. When this RNA preparation was first fractionated by sucrose gradient centrifugation, the 77K protein appeared to be synthesized from messenger RNA with a sedimentation coefficient of 25S-35S. (56 refs)

- 79-2719 **Antigenic Properties and Molecular Weights of Murine Leukemia Virus-binding Proteins.** (Eng) Baird, S. M. (Veterans Admin., VA Medical Center, San Diego, CA) *J Immunol* 122(4): 1389-1396; 1979.

A murine T lymphoma cell line, WEHI-22, was studied for the presence of murine leukemia virus-binding proteins and for the presence of cell-surface molecules that share antigens with mouse immunoglobulins (Ig's). Surface radioiodination, detergent disruption, and immunoprecipitation techniques identified a 60,000- to 70,000-dalton polypeptide that was recognized by chicken anti-mouse Ig serum. This serum did not detect a molecule similar to the WEHI-22 molecule on normal thymocytes. In competition experiments, this molecule cross-reacted with highly purified mouse IgM myeloma proteins. A cell-

surface molecule of similar size was shown to bind to murine leukemia viruses. Precipitation of the WEHI-22 cell surface material with chicken anti-mouse Ig removed the material binding to the leukemia viruses. (25 refs)

- 79-2720 **Genetic Linkage of C3H/HeJ and BALB/c Endogenous Ecotropic C-Type Viruses to Phosphoglucomutase-1 on Chromosome 5.** (Eng) Ihle, J. N. (Cancer Biology Program, Frederick Cancer Res. Center, Frederick, MD 21701); Joseph, D. R.; Domotor, J. *J. Science* 204(4388): 71-73; 1979.

Serological assays of backcrossed mice were used to demonstrate the apparent allelism of BALB/c and C3H/HeJ endogenous ecotropic C-type viral loci on chromosome 5. In the backcross C57BL/6 x (C57BL/6 x C3H/HeJ), there is a clear segregation of the C3H/HeJ phenotype, in that individual mice are either antibody-positive early in life and remain antibody-positive or they remain antibody-negative. In 208 backcrossed mice, 51.4% were of the C3H/HeJ phenotype, which suggests that a single gene locus controls the serological phenotype. Using the same backcross, no apparent linkage of the C3H/HeJ phenotype with a variety of isoenzyme markers (serum esterase-1, serum esterase-3, glucose-6-phosphate dehydrogenase-1, the agouti locus, the locus for the β chain of Hb, the histocompatibility locus, or malate dehydrogenase) was found. However, linkage was apparent with phosphoglucomutase-1 (*Pgm-1*), in that only 40/141 mice examined were of the recombinant phenotype. These results demonstrate that the C3H/HeJ viral locus (*C3v*) is on chromosome 5 and is linked to *Pgm-1*. Further experiments demonstrated that the BALB/c and C3H/HeJ loci are either allelic or closely linked on chromosome 5, in contrast to the C57BL/6 viral locus, which is not allelic and probably is not linked to the C3H/HeJ locus. (22 refs)

- 79-2721 ***Fv-1* Restriction of Xenotropic and Amphotropic Murine Leukemia Virus Genomes Phenotypically Mixed with Ecotropic Virus.** (Eng) Ishimoto, A. (Lab. Viral Diseases, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD 20014); Hartley, J. W.; Rowe, W. P. *Virology* 93(1): 215-225; 1979.

Xenotropic murine leukemia virus (MuLV) genomes rendered capable of infecting mouse cells by phenotypic mixing with an ecotropic MuLV exhibited the *Fv-1* restriction pattern of that ecotropic virus. Like *Fv-1*-restricted ecotropic viruses, xenotropic genomes phenotypically mixed with N-tropic ecotropic MuLV showed two-hit dose-response kinetics when titrated on restrictive *Fv-1b* cells; the kinetics were converted to one-hit by the addition N-tropic ecotropic virus. When SC-1 cells chronically infected with N-tropic amphotropic MuLV were superinfected with B-tropic ecotropic virus, each genome tended to maintain

its homologous tropism, but with intermediate N:B infectivity ratios that changed between the acute and chronic phases of infection. In clonal lines chronically producing both viruses, the relative N- or B-tropism of the two genomes tended to vary in the same direction, and this correlated with the genome that was produced in greater abundance. The results suggest that (1) there is some recognition of amphotropic and ecotropic genomes by their homologous *Fv-1* tropism determinants, and (2) that the tropism of the virions in the mixed harvest is determined by this recognition factor and by the relative abundance of the two types of determinant. (30 refs)

- 79-2722 Defective Retrovirus-like 30S RNA Species of Rat and Mouse Cells Are Infectious if Packaged by Type C Helper Virus.** (Eng) Scolnick, E. M. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD 20014); Vass, W. C.; Howk, R. S.; Duesberg, P. H. *J Virol* 29(3): 964-972; 1979.

Cell lines that express high levels of a 30S defective retroviruslike (DRV) RNA were used to form pseudotypes of the 30S RNA's with helper-independent C-type viruses. A pseudotype virus complex containing a mouse 30S subunit was transmitted to rat cells, and a pseudotype virus complex containing a rat 30S subunit was transmitted to bat cells. In addition, a rat 30S subunit was isolated in non-producer bat cells without detectable expression of the helper-independent C-type virus used to pseudotype it. The transmissibility of an endogenous rat 30S subunit to heterologous nonproducer cells extends the similarity between the 30S subunit and other replication-defective retroviruses and is consistent with the provirus hypothesis. The function of the 30S DRV RNA in mouse and rat cells is not known, and cells expressing these RNA's and releasing them as viral pseudotypes do not appear morphologically transformed in culture. Relatively low levels of rat 30S DRV RNA were detected in rat cells and bat cells, and it is possible that morphological transformation may depend on a critical threshold concentration. It is also possible that the oncogenicity in animals of certain mouse and rat cell lines considered untransformed in culture may be related to the presence and concentration of 30S DRV RNA, which may function directly in neoplastic transformation in the animal or could become active only by recombination with some other viral or cellular gene. (27 refs)

- 79-2723 Virus-like 30S RNA in Mouse Cells.** (Eng) Besmer, P. (Hadassah Medical Sch., Hebrew Univ., Jerusalem, Israel); Olshevsky, U.; Baltimore, D.; Dolberg, D.; Fan, H. *J Virol* 29(3): 1168-1176; 1979.

Particles released from JLS-V9 cells, a cell line derived from BALB/c mice, after induction with bromodeox-

yuridine (BrdU) were characterized biochemically. After heat denaturation, most of the RNA in particles released after BrdU treatment (BU-V9 virus) migrated as 30S RNA material during electrophoresis through agarose gels. This viruslike 30S RNA (VL30) could be packaged in virus particles, could polymerize to a 50S form, and could be reverse-transcribed. Annealing experiments of BU-V9 complementary DNA (cDNA) to cytoplasmic RNA's from other cells revealed that VL30 RNA sequences are expressed in other mouse cells, eg, NIH/3T3, but not in heterologous (rat, rabbit, or mink) cells. Fingerprint analysis and hybridization studies indicated that VL30 RNA does not have homology with the standard nondefective murine leukemia viruses (MuLV's). Upon superinfection with a nondefective MuLV or upon induction of endogenous virus with BrdU, VL30 RNA was rescued into virions by phenotypic mixing. When VL30 RNA was rescued by BrdU induction, it was mainly as a 50S complex, but when it was rescued by superinfection, VL30 was also found in 70S RNA. Hybridization of a cDNA probe to cellular RNA immobilized on paper revealed that no subgenomic RNA related to the VL30 RNA is present in cells expressing the VL30 sequences. VL30 RNA is apparently from a new class of endogenous defective retroviruses and is probably present in most stocks of leukemia and sarcoma viruses made in mouse cells, considerations that must be taken into account when carrying out hybridization experiments with MuLV's. - 79-2724 Association of Productive Murine Leukemia Virus (MuLV) Infection with Enhanced H-2 Antigen Expression on Murine Lymphoblastoid Cells (Meeting Abstract).** (Eng) Henley, S. L. (Univ. Alabama Birmingham, Birmingham, AL 35294); Acton, R. T.; Wise, K. S. *Fed Proc* 38(3, part 2): 927; 1979 (no refs)

- 79-2725 Antiserum to Murine Leukemia Virus Recognizes Novel Cell Surface Molecules Associated with Growth Control and Transformation.** (Eng) Rieber, M. (Center Microbiology and Cell Biology, Instituto Venezolano de Investigaciones Cientificas, Apartado 1827, Caracas, Venezuela); Rieber, M.; Alonso, M. *Int J Cancer* 23(4): 547-554; 1979.

Data on the nature and surface localization of antigenically related molecular species and on their relationship to growth control are presented. Antiserum directed against murine leukemia virus (MuLV) also reacts with several external proteins present in rat cells transformed by a temperature-sensitive Rous sarcoma virus (RSV). Reaction of iodinated cell extracts with anti-MuLV serum revealed the presence of a 200,000-dalton iodinated component detectable also by metabolic labeling with glucosamine only in serum-starved cultures restricted in the expression of transformation. A similar assay with iodinated cells that

express the transformed phenotype revealed the preferential recognition of two components with an approx mol wt of 100,000 daltons as well as an additional 65,000-dalton external component. Growth of the transformed non-producer NT₃-KR cells (cloned derivative from the normal rat kidney line transformed by a temperature-sensitive derivative of the B77 strain of RSV) in the presence of inducers of C-type viruses led to increased synthesis of a 100,000-dalton glycoprotein (gp100) recognized by the anti-MuLV serum, which is also recognized by the antiserum in NRK-MSV-MuLV-transformed producer cells, in addition to a viruslike glycoprotein of 71,000 daltons (gp71). Absorption of the anti-MuLV serum with monolayers of NT₃-KR cells eliminated the ability of the serum to recognize the gp100, but not the gp71, from NRK-MSV-MuLV-transformed producer cells. The mediation of posttranslational changes in growth control is suggested by the transformation-dependent alteration in the mol wt of the nonviral surface proteins recognized by anti-MuLV serum in the rat cells. 79-2726 Immunoglobulin Production by Lymphosarcomas Induced by Abelson Virus in Mice.

(Eng) Potter, M. (Lab. Cell Biology, Public Health Service, U.S. Dept. Health, Education and Welfare, NCI, NIH, Bethesda, MD 20014); Premkumar-Reddy, E.; Wivel, N. A. *Natl Cancer Inst Monogr* (48): 311-320; 1978.

Electron microscope studies of undifferentiated lymphosarcomas (LS) and plasmacytic lymphosarcomas (PL) induced in BALB/c mice by Abelson murine leukemia virus showed that both tumor types may be mixed and contain undifferentiated cells or cells with a moderate amount of rough endoplasmic reticulum and polysomes. However, PL tumors are composed predominantly of the latter. In biosynthetic studies, PL tumors produced more immunoglobulin (Ig) than LS and more of the heavy chain Ig that is thought to be the murine counterpart of IgD. PL cells sensitized with rabbit antisera to mouse kappa chains formed rosettes with formalinized protein-A producing *Staphylococcus aureus* Cowan I strain. The rabbit antisera were specific for kappa chains by absorption. The failure of lymphosarcoma cells to secrete Ig indicates that their differentiation is blocked by the transformation process. Therefore, lymphosarcoma cells appear to be derived from B lymphocytes. (no refs)

79-2727 Cell-Surface Antigens Associated with Recombinant Mink Cell Focus-inducing Murine Leukemia Viruses. (Eng) Cloyd, M. W. (Lab. Viral Diseases, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD 20014); Hartley, J. W.; Rowe, W. P. *J Exp Med* 149(3): 702-712; 1979.

The purpose of this study was to characterize reagent antisera made against AKR mink cell focus-inducing (MCF) murine leukemia viruses (MuLV's) and to characterize the cell-surface antigens induced by naturally occurring mouse MCF viruses. Distinct type-specific antigens were detected on cells infected with cloned MCF MuLV's by cell-surface immunofluorescence absorption assays with rabbit antisera raised against naturally occurring AKR MCF viruses. The MCF type-specific antibodies were present in high titer and not absorbable by cells infected with ecotropic, xenotropic, or wild mouse amphotropic MuLV's or with combinations of ecotropic and xenotropic viruses. Three MCF subtype-specific reactions were identified. One subspecificity (operationally designated MCFA-1) defined antigenic determinant(s) distributed among MCF viruses in general. Another (MCFA-2) specified determinant(s) induced by all naturally occurring MCF isolates not of Friend or Moloney origin. A third subspecificity (MCFA-3) was induced by some MCF isolates, and not by others; the presence of this antigen did not correlate with the source of any presently known biological property of the viruses. In addition, type-specific antigenic determinants of ecotropic and xenotropic MuLV's were expressed on MCF virus-infected cells. The serological profile of MCF viruses thus supports the contention that they are *env* gene recombinants between ecotropic and xenotropic MuLV's. However, new, distinct MCF-specific determinants are also generated, and these could be useful markers in studying MCF viruses. (18 refs)

79-2728 Properties of Mouse Leukemia Viruses. XVI. Suppression of Spontaneous Fatal Leukemias in AKR Mice by Treatment with Broadly Reacting Antibody Against the Viral Glycoprotein gp 71. (Eng) Schwarz, H. (Max-Planck-Institut für Virusforschung, Tübingen, W. Germany); Fischinger, P. J.; Ihle, J. N.; Thiel, H. J.; Weiland, F.; Bolognesi, D. P.; Schafer, W. *Virology* 93(1): 159-174; 1979.

AKR mice were treated early in life with antibodies prepared in a goat against the major glycoprotein (gp71) of Friend murine leukemia virus (FLV) and evaluated for up to 2 yr for various parameters associated with AKR thymoma/lymphoma. When both mothers and neonates were given the antibody, AKR disease was suppressed to the degree that the 50% incidence of leukemia was delayed by about 1 yr. The treatment was less effective if initiated at age 3 days, and administration of the antibody to mothers alone or to mice at age 39 days was not successful. Thus, the critical period for treatment was between birth and the first few days of life. Postmortem examination of animals that were treated during this early period revealed a unique leukemic pattern in that the frequency of B-type leukemia (lymphoma only) nearly equaled that of A-type leukemia (thymoma + lymphoma). In addition, several mice died from nonmalignant disease and one died from a lung adenoma. Overall, successful antibody treatment resulted in suppression of virus and development of signifi-

cant levels of antiviral antibodies. Control mice exhibited the opposite pattern: high levels of virus and no detectable antibody. Moreover, the antibody suppressed the expression of mink cell focus-inducing type recombinant virus in tumors of treated mice. It is hypothesized that the heterologous antibody disturbed a key event that occurs during the early life of the AKR mouse and that is of critical importance for the development of leukemia from age 6 mo onward. (35 refs)

- 79-2729 Correlation of the Induction of Transcription of the AKR Mouse Genome by 5-Iododeoxyuridine with the Activation of an Endogenous Murine Leukemia Virus.** (Eng) Chattopadhyay, S. K. (Building 10, Room 2B-50, NIH, Bethesda, MD 20014); Jay, G.; Lander, M. R.; Levine, A. S. *Cancer Res* 39(5): 1539-1546; 1979.

The possibility that incorporated 5-iododeoxyuridine (IdUrd) qualitatively alters the transcription of cell DNA was studied with the use of the highly activatable mouse embryo cell line AKR-2B. Nucleic acid hybridization between radioactive mouse-unique DNA and RNA from AKR-2B cells indicated that the normal extent of transcription in AKR-2B cells is considerably lower than that observed in other mouse cell lines studied (SC-1, NIH 3T3, BALB/c 3T3, and NIH Swiss). Treatment of AKR-2B cells with IdUrd increased the extent of transcription of unique DNA by 60%, which corresponds to an induction of approx 2.5×10^4 gene equivalents. Included among this new set of RNA's were sequences transcribed from the DNA genome of the endogenous AKR-type murine leukemia virus present in AKR-2B cells. IdUrd treatment also markedly increased the synthesis and/or accumulation of those RNA transcripts that are normally expressed in untreated cells. These results suggest that IdUrd stimulates the overall transcription of AKR-2B cells. IdUrd-induced activation of endogenous murine leukemia virus may be a consequence of this stimulation. (39 refs)

- 79-2730 Interaction of Leukemia Viruses with Cells of the Immune Response System.** (Eng) Friedman, H. (Dept. Microbiology, Univ. South Florida Coll. Medicine, Tampa, FL 66312); Specter, S. *Transplant Proc* 11(1): 1060-1065; 1979.

The effects of the Friend leukemia virus (FLV) complex on in vivo and in vitro immune responses were studied in BALB/c and DBA mice. Spleen cells from infected animals were injected into heavily irradiated recipient mice, which were then challenged with sheep RBC and examined for their antibody response. Donor mice, infected for 7-10 days or longer, showed an 80%-90% or greater suppression of antibody responsiveness to sheep RBC. The B cell precursors in the bone marrow were more impaired than

the T lymphocytes. Spleen cells from FLV-infected animals also exhibited depressed immune responses in vitro. In addition, infected splenocytes added in relatively small numbers to normal spleen cells in vitro resulted in immunosuppression. Separation of the immunosuppressive infected spleen cells from normal cells by cell-impermeable membranes (0.45 μ m pore size) still resulted in immunosuppression, indicating that a virus or virus-associated agent crossed the membrane and depressed immunity. Anti-FLV serum neutralized this suppression. Cell-free extracts, but not unclarified extracts, from infected spleens also inhibited antibody formation when added to normal spleen cells in culture. Electron microscopy and fluorescent antibody studies indicated that the number of splenocytes with the normal surface topography of lymphoid cells was decreased in the spleens of infected animals. These changes were correlated with decreased numbers of splenocytes evincing surface immunoglobulin and theta antigen and increased numbers positive for FLV-associated surface antigen. (14 refs)

- 79-2731 Alterations in the Response to Erythropoietin and RNA-dependent DNA Polymerase Activity in Mouse Spleen Cells Infected with Friend Leukemia Virus.** (Eng) Horikoshi, A. (First Dept. Internal Medicine, Nihon Univ. Sch. Medicine, Oyaguchi, Itabashi, Tokyo 173, Japan); Sasaki, R.; Mizoguchi, H.; Miura, Y.; Takaku, F.; Amaki, I. *Cancer Res* 39(5): 1841-1846; 1979.

Changes in heme synthesis, in responsiveness to erythropoietin in vitro, and in RNA-dependent DNA polymerase activity (RDDP) of mouse spleen cells were determined after the ip inoculation of C3H/He mice with about 2×10^4 spleen focus-forming units of Friend leukemia virus (FLV). By day 6 following FLV injection, hyperbasophilic "Friend cells" resembling proerythroblasts became dominant in the spleen. The heme synthesis rate in the infected spleen cells started to increase 14 days after infection, and it reached a plateau at a level about five times higher than that of the uninfected control spleen cells after about 22 days. Although a normal response to erythropoietin was observed 4 hr after infection, no response could be detected at 24 hr and thereafter. RDDP activity in the spleen cells began to increase on day 4, attaining a peak on days 8 and 10 and decreasing markedly thereafter. Enzyme activity again increased on day 28. These results suggest that FLV affected the erythropoietin-responsive cells at a very early stage of infection, before morphological changes in the spleen cells or increases in RDDP activity could be observed. (45 refs)

- 79-2732 Erythroid Leukemia Induced by Friend Lymphatic Leukemia Virus in T-Cell-depleted Mice.** (Eng) Dawson, P. J. (Dept. Pathology, Univ. Chicago, 950 E. 59th St., Chicago, IL 60637); Dresler, S. L.; Fieldsteel, A. H. *Cancer Res* 39(5): 1611-1615; 1979.

The possibility that the production of different leukemias in intact and thymectomized mice is due to the selective expression of different components from a mixture of leukemia viruses was investigated. BALB/c mice depleted of T cells by thymectomy at 3-5 days of age and by treatment with antithymocyte serum were inoculated with Friend virus-associated lymphatic leukemia virus (LLV-F). After a long latent period, these animals developed erythroid leukemia. In contrast, intact control mice inoculated with LLV-F developed typical T-cell lymphomas. Cell-free virus prepared from leukemic T-cell-depleted animals induced lymphoid, myeloid, and erythroid leukemias in intact mice. The erythroid leukemia-inducing virus differed from the spleen focus-forming component of Friend virus in its long latent period (88-225 days) and in its inability to induce spleen foci. End-point dilution experiments suggested that a hitherto undescribed component of the Friend virus complex might be responsible for these late-appearing erythroid leukemias. (14 refs)

- 79-2733** Enhanced Expression of Viral Polypeptides and Messenger RNA in Dimethyl Sulfoxide and Bromodeoxyuridine-treated Friend Erythroleukemic Cells. (Eng) Colletta, G. (Chair Viral Oncology, Inst. General Pathology, 2nd Faculty Medicine and Surgery, Univ. Naples, I-80131 Naples, Italy); Fragomele, F.; Sandomenico, M. L.; Vecchio, G. *Exp Cell Res* 119(2): 253-264; 1979.

The intracellular virus-specific macromolecular changes induced by dimethyl sulfoxide (DMSO) and/or bromodeoxyuridine (BUdR) were analyzed in the Friend erythroleukemic cell (FLC) clone 745 A 19. These cells, which were transformed in vivo by Friend virus, are arrested in an undifferentiated state but can be induced to differentiate in vitro by DMSO. Treatment of FLC's with 2% DMSO for 4 days enhanced extracellular virus production and, concomitantly, increased by about four-fold intracellular virus-specific polyribosomal RNA. The simultaneous addition to FLC's of DMSO and BUdR (the latter inhibits DMSO-induced differentiation) brought about an even greater increase in both viral polypeptides and viral messenger RNA (mRNA). As a consequence of treatment with both drugs, new viral nucleotide sequences were expressed, as revealed by nucleic acid hybridization studies. Moreover, it appears that two p30-like virus-specific intracellular polypeptides, instead of one single p30, were expressed in FLC's treated with DMSO and BUdR. These data also support the idea that gene sequences different from those present in the original Friend virus are expressed as a consequence of the combined treatment. It is concluded that the main site of action of both drugs in this cell system is at the level of transcription of viral RNA, and it is suggested that the drugs may act upon cell differentiation by modulating the expression of integrated viral genomes differently. (38 refs)

- 79-2734** Enhancement of Erythroid Target Cells for Friend Murine Leukemia Virus by Intravenous Pyran Treatment. (Eng) Schuller, G. B. (Dept. Surgery, Medical Coll. Virginia, Virginia Commonwealth Univ., Richmond, VA 23298); Morahan, P. S. *J Natl Cancer Inst* 62(5): 1257-1260; 1979.

The enhancement of Friend murine leukemia virus (F-MuLV) leukemogenesis by pyran, a synthetic polyanionic immunomodulator, was investigated. Male BALB/c mice that received prophylactic treatment with pyran (25 mg/kg iv) had significantly enhanced splenomegaly, an increased number of splenic foci induced by the spleen focus-forming virus (SFFV) in the F-MuLV complex, and a slightly decreased mean survival time compared with untreated controls infected with F-MuLV. A corresponding increase in the lymphatic leukemia virus component of the F-MuLV complex was not observed, which suggests that the enhancement of the disease was due primarily to a selective increase in the SFFV component of the F-MuLV complex. That the enhancement was related to an increased number of target cells for SFFV was substantiated by data concerning erythropoiesis in iv pyran-treated animals. Increases in splenic hematocrits and in uptake of ^{59}Fe in the spleens of animals treated with pyran provided quantitative evidence for the histologic finding of increased erythroid precursors in the spleens. (22 refs)

- 79-2735** Expression of *Fv-4r* Allele in Hematopoietic Cells from G Mice Resistant to Friend Leukemia Virus. (Eng) Ikeda, H. (Dept. Genetics, Inst. Medical Science, Univ. Tokyo, P.O. Takanawa, Tokyo 108, Japan); Odaka, T. *Int J Cancer* 23(4): 514-518; 1979.

Susceptibility to Friend leukemia virus (FLV) infection was studied in radiation chimeras between G mice carrying the *Fv-4*-resistant allele and *Fv-4*-susceptible DDD mice. The helper lymphatic leukemia virus (LLV) of FFV did not replicate in FFV-infected G mice, and virus growth was not enhanced by treatment with cyclophosphamide or cortisone acetate. Reciprocal bone marrow or spleen cell transplantation between G and DDD or DDD-*Fv-r* mice converted the susceptibility of the recipients to that expected from the genotypes of the donors. However, G mice reconstituted with DDD or DDD-*Fv-r* cells were not as susceptible as DDD mice reconstituted with DDD or DDD-*Fv-r* cells. Reconstituted G mice showed lower LLV and spleen focus-forming virus titers than did similarly reconstituted DDD mice, and they developed splenomegaly after a longer latent period. It is concluded that helper LLV grows mainly in the radiosensitive, bone marrow-derived cells and that the *Fv-4* gene is expressed in these cells. (18 refs)

- 79-2736** In Vitro Transformation of Mouse Bone Marrow Cells by the Polycythemic Strain of Friend

Leukemia Virus. (Eng) Revoltella, R. (Dept. Tumor Immunobiology, Lab. Cell Biology, Consiglio Nazionale delle Ricerche Rome, Rome, Italy); Bertolini, L.; Friend, C. *Proc Natl Acad Sci USA* 76(3): 1464-1468; 1979.

Strains of Friend leukemia virus (FLV) that are associated with polycythemia contain the defective spleen focus-forming virus (SFFV). The ability of these FLV strains to transform DBA/2J mouse bone marrow cells in vitro was studied in an effort to clarify the role that SFFV may play in the pathogenesis of leukemia in vivo. Criteria for transformation were the establishment of permanent lines, growth on semisolid agarose, and the production of tumors at the inoculation site in syngeneic hosts. Two lines of immature hematopoietic cells that grew in suspension originated from the infected cultures. Each had an almost diploid karyotype (38-39 chromosomes) and 3-4 metacentric chromosomes. These transformed cells expressed the gp71 viral envelope glycoprotein and p30 viral core protein antigens. Virus production was measured by the reverse transcriptase (RNA-dependent DNA polymerase) activity of the virions released into the medium. The virus, assayed in vivo for infectivity, had SFFV activity but was attenuated for leukemogenicity. The stimulation of Hb synthesis in cells grown in medium supplemented with dimethyl sulfoxide or hexamethylene bisacetamide indicated that the cells are erythroid in origin. SFFV may have a function analogous to that of erythropoietin in influencing the process of transformation by FLV. (32 refs)

79-2737 Replication-defective S+L- Moloney MSV Codes for an Envelope Glycoprotein with Moloney MuLV- and MCF-MuLV-specific Determinants. (Eng) Reynolds, F. H. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD 21701); Rapp, U. R.; Todaro, G. J.; Stephenson, J. R. *Virology* 93(2): 582-588; 1979.

The expression of a recombinant envelope glycoprotein containing mink cell focus-forming (MCF)-specific determinants in cells nonproductively transformed by the S + L-strain of Moloney murine sarcoma virus (Mo-MSV) is reported. Cells nonproductively transformed by the S + L-strain of Mo-MSV expressed three *gag* gene components, p15, p12, and p30, in the form of a 55,000-mol wt precursor polypeptide. In addition, these transformed cell lines were characterized by expression of an envelope glycoprotein containing antigenic determinants related to those of both Moloney murine leukemia virus and viruses of the previously described highly leukemogenic MCF group. These cells lacked detectable reactivity in competition immunoassays for either the carboxy-terminal *gag* gene protein, p10, or C-type viral reverse transcriptase. Cells transformed by either of two other Mo-MSV isolates lacked detectable levels of expression of any of the known *gag* or *env* gene-coded proteins. These findings indicate that although recombination within C-type virus structural

genes may be involved in the genesis of mammalian sarcoma viruses, expression of viral structural proteins is not necessary for malignant transformation. (29 refs)

79-2738 Functional Activity of Murine Lymphocytes During Viral Carcinogenesis. (Rus) Umanskii, Iu. A. (Dept. Immunology Carcinogenesis, Inst. Problems Oncology, Kiev, USSR); Evsev'eva, A. I.; Semenova-Kobzar', R. A.; Kushko, L. Ia. *Tsitologiya* 21(2): 191-195; 1979.

The functional activity of lymphocytes from BALB/c mice with a Moloney virus-induced sarcoma was evaluated. Animals were inoculated im with a 10% extract of tumor tissue and, within different time periods after inoculation, the antitumor activity of the lymphocytes and their ability to undergo phytohemagglutinin (PHA)-induced blast transformation (BT) was determined. On days 7-8 after virus inoculation (ie, during tumor progression), the BT activity of the lymphocytes was nine times lower than that of lymphocytes from control mice. On days 13-15 after virus administration (ie, during tumor regression) the lymphocytes showed a 4.2-fold increase in BT activity. (21 refs)

79-2739 Immune Responses to Weakly Immunogenic Virally Induced Tumors. III. Genetically Unrestricted Cytolysis of Allogeneic Tumor Target Cells. (Eng) Devens, B. (Lautenberg Center General and Tumor Immunology, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Naor, D. *J Immunol* 122(4): 1397-1401; 1979.

The genetically nonrestricted cytotoxicity of allogeneic tumor target cells was investigated using in vitro- or in vivo-passaged YAC, a Moloney virus-induced lymphoma of A mice (H-2a), and RBL5, a Rauscher virus-induced lymphoma of C57BL/6 mice (H-2b). These tumors cross-react serologically. Splenocytes from A mice injected with in vitro-passaged YAC-1 or with RBL5 could generate, after in vitro culture with or without stimulation, a genetically nonrestricted cytotoxic response against RBL5. The effector cells that were generated after the in vitro cultivation recognized tumor-associated antigens (TAA) on the target cells. H-2 alloantigens were not recognized by the effector cells. The effector cells that killed RBL5 tumor cells in a genetically nonrestricted manner were identified as T cells. In vivo-passaged YAC did not induce anti-RBL5 reactive cells in A mice. Instead, it induced suppressor cells that could abrogate the anti-RBL5 cytotoxic response of RBL5-primed splenocytes but not that of YAC-1 primed splenocytes. This suggests that the reactive cells generated after RBL5 injection are different from the reactive cells generated after YAC-1 injection. (18 refs)

VIRAL CARCINOGENESIS

- 79-2740 Amino Acid Sequence Homology Between Histone H5 and Murine Leukemia Virus Phosphoprotein p12.** (Eng) Henderson, L. E. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD 21701); Gilden, R. V.; Oroszlan, S. *Science* 203(4387): 1346-1348; 1979.

Amino acid sequences of the conserved regions near the amino termini of several murine leukemia virus (MuLV) p12 phosphoproteins were compared with those of the H5 histones. H5 histones are phosphorylated nuclear proteins found only in nucleated RBC. Comparison of residues 4-15 in goose H5 with residues 1-12 in Moloney MuLV showed 6 positional identities out of 12 residues without the introduction of a gap in either sequence. The number of identities increased with the introduction of gap at position 13 in the alignment of the H5 sequences. Functionally homologous amino acid residues also appeared in positions 2, 4, 8, 9, 12, 14 and 15. Apparent amino acid sequence similarities between human immunoglobulins and the p12 proteins appeared to be the result of chance and the method of comparison. Conversely, the H5 histones and viral p12 proteins appeared to be under selective pressure to conserve the highly related sequences in a coiled structure near the amino acid terminal regions. It is unlikely that the two groups of proteins evolved from a single common ancestral gene, but evolution of retrovirus structural proteins by a process of differentiation from preexisting cellular genes is likely. The amino terminal sequence homology between viral p12 proteins and the H5 histones suggests that the amino terminal regions of the p12's may also be involved in nucleic acid binding and/or phosphorylation. (25 refs)

- 79-2741 Isolation and Characterization of a Mouse Cell Line Containing a Defective Moloney Murine Leukemia Virus Genome.** (Eng) Besmer, P. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA 02139); Fan, H.; Paskind, M.; Baltimore, D. *J Virol* 29(3): 1023-1034; 1979.

Mouse JLS-VII cells containing a 1,000-nucleotide deletion mutant of Moloney murine leukemia virus (M-MLV) were cultured and characterized. The deletion did not affect the size or function of the 21S messenger RNA (mRNA) that encodes the *env* gene products. Both the deleted RNA and the 21S mRNA were recovered in polyribosomes. Cells containing the deleted virus made no detectable Pr180gag-pol. Pr65gag synthesis was also absent, but a 45,000-mol-wt gag gene product was found that might be encoded by the deleted genomes. Biosynthesis of Pr80env proceeded normally in these cells; the intracellular precursor was cleaved and migrated to the cell surface as gp70. The cells could not be superinfected by homologous M-MLV, presumably because of surface restriction due to the gp70. Although the cells expressed M-MLV gp70 on their surface, they did not make pseudotypes after infection with

vesicular stomatitis virus, which suggests that PR65 gag may play a critical role in pseudotype formation. Induction of endogenous virus expression in the cells carrying the deletion mutation generated an N-tropic MLV that could fuse XC cells. This may represent a recombinant between the deletion mutant and an endogenous virus. (59 refs)

- 79-2742 Maturation of Moloney Murine Leukemia Virus.** (Eng) Lu, A. H. (Dept. Microbiology, Sch. Basic Medical Science, Univ. Illinois, Urbana, IL 61801); Soong, M. M.; Wong, P. K. *Virology* 93(1): 269-274; 1979.

Virion changes during the membrane postbudding process were studied using freshly released virions of a temperature-sensitive mutant (ts3) of Moloney murine leukemia virus. Cultured TB cells, a CFW/D mouse thymus-bone marrow line, were infected with ts3 and grown at 39 C (nonpermissive temperature) until semiconfluent; the virions were then collected from the culture supernatant beginning 30 min after the cultures were shifted to 34 C. Virions released at 34 C showed a twofold increase in infectivity and reverse transcriptase activity for the first 90-120 min after release. Upon further incubation, both infectivity and reverse transcriptase activity decreased. Furthermore, processing of the gag precursor was also observed. These postrelease changes were found to be correlated with the morphologic transformation of immature to mature virions. (15 refs)

- 79-2743 Cell-free Synthesis of Rauscher Murine Leukemia Virus "gag" and "env" Gene Products from Separate Cellular mRNA Species.** (Eng) Murphy, E. C. (Dept. Biology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX 77030); Campos, D.; Arlinghaus, R. B. *Virology* 93(2): 293-302; 1979.

RNA from cells infected with Rauscher murine leukemia virus (R-MuLV) was translated in a messenger RNA (mRNA)-dependent cell-free protein synthesizing system. A cellular RNA species of about 35S in size coded for polypeptides of approx 65,000 mol wt (Pr65gag) and 200,000 mol wt (Pr200gag) that were immunoprecipitable with antisera directed against the R-MuLV gag proteins p30, p15, p12, and p10. The methionine-containing tryptic peptides of the 65,000-mol wt polypeptide translated from cellular 35S RNA were identical to those of authentic Pr65gag. Translation of RNA in the 25S-35S size class suggests that although Pr65gag can be translated by RNA throughout this size range, Pr200gag-pol translation is restricted to mRNA that sediments at 35S. Antiserum directed against the R-MuLV envelope protein gp69/71 recognized a polypeptide of 68,000 mol wt, designated Pr68env, that was coded for by RNA that sedimented at

about 22S in sucrose gradients and had a minimum size of about 1.25×10^6 daltons, as estimated by agarose gel electrophoresis. Tryptic maps of Pr68env showed that it contained all of the methionine-labeled tryptic peptides and most of the tyrosine-containing tryptic peptides characteristic of gPr90env, the authentic R-MuLV glycosylated envelope precursor. (25 refs)

- 79-2744 Identification of a Mouse Gene Required for Binding of Rauscher MuLV Envelope gp70.** (Eng) Hilkens, J. (Div. Genetics, Netherlands Cancer Inst., Plesmanlaan 121, 1066 CX Amsterdam, Netherlands); Colombatti, A.; Strand, M.; Nichols, E.; Ruddie, F. H.; Hilgers, J. *Somatic Cell Genet* 5(1): 39-49; 1979.

The genetics of the receptor for ecotropic murine leukemia virus (MuLV) infection was studied in somatic cell hybrids. Mouse chromosome-segregating somatic cell hybrids were established between a mouse thymic leukemia cell line (GRSL) and a Chinese hamster lung fibroblast line (E36). The GRSL cells specifically bound purified Rauscher MuLV envelope glycoprotein gp70, but the E36 cells exhibited no binding. The hybrids selectively bound Rauscher gp70, depending on the presence of a mouse cellular gene for the ecotropic MuLV gp70 receptor. A syntenic relationship was observed between the dipeptidase-3 chromosome marker (on chromosome 5) and the gp70 receptor in primary clones and subclones of these hybrids; this relationship was confirmed by chromosome analysis. The involvement of the major histocompatibility (H-2) antigens in the binding of Rauscher MuLV gp70 could be ruled out, because discordancies of the receptor presence/H-2 absence as well as of the receptor absence/H-2 presence type were observed. These results indicate that the *Rec-1* (replication ecotropic MuLV) gene may be the receptor gene for ecotropic MuLV. (31 refs)

- 79-2745 Tunicamycin Inhibits Glycosylation of Precursor Polyprotein Encoded by env Gene of Rauscher Murine Leukemia Virus.** (Eng) Schultz, A. M. (Frederick Cancer Res. Center, Frederick, MD 21701); Oroszlan, S. *Biochem Biophys Res Commun* 86(4): 1206-1213; 1979.

The effect of tunicamycin on the synthesis and processing of the viral envelope precursor polyprotein (gPr85env) of Rauscher murine leukemia virus (R-MuLV) was investigated in BALB/c mouse bone marrow cells. Tunicamycin specifically inhibits the synthesis of oligosaccharides that attach to glycoproteins via asparagine residues. The mol wt of this precursor polyprotein was reduced from 85,000 to 68,000 daltons when it was synthesized in the presence of tunicamycin. The unglycosylated precursor protein (Pr68env) was synthesized at a rate comparable to that of the normal carbohydrate-

containing envelope precursor (gPr85env). Pr68env was not proteolytically processed, and it remained undegraded in the cell. Thus, most, if not all, of the carbohydrate content of gPr85env is N-linked, and glycosylation appears to be necessary for normal processing of precursor proteins into viral particles. (28 refs)

- 79-2746 Properties of "Mink Cell Focus-inducing" (MCF) Virus Isolated from Spontaneous Lymphoma Lines of BALB/c Mice Carrying Moloney Leukemia Virus as an Endogenous Virus.** (Eng) Vogt, M. (Tumor Virology Lab., Salk Inst., P. O. Box 1809, San Diego, CA 92112) *Virology* 93(1): 226-236; 1979.

Mink cell focus-inducing (MCF) viruses were isolated from lymphoid cell lines derived from five spontaneous thymomas of BALB/c (Mo) mice. The Mo-MCF isolates grew both in murine and nonmurine cells, were interfered with by both ecotropic and xenotropic murine leukemia viruses (MuLV), and were NB-tropic. They also induced cytopathic changes in mouse cells. In cells producing both Mo-MCF and Mo-MuLV, Mo-MCF genomes were predominantly released as pseudotypes with Mo-MuLV envelopes. Mo-MCF was weakly lymphomagenic in NIH Swiss mice, inducing thymomas in only 3/35 mice inoculated sc with 650-4,500 focus-forming units of virus. However, each cell in a BALB/c (Mo) thymoma line and each cell in a Mo-MCF-induced thymoma produced MCF virus, which suggests that MCF viruses are required for lymphomagenesis. Mo- and AKR-MuLV might play a double role in the development of spontaneous lymphomas: (1) as parental viruses by generating MCF recombinants and (2) as helper viruses by forming pseudotypes of MCF viruses. (28 refs)

- 79-2747 Effect of Interferon on Human Cells Releasing Oncornaviruses: An Assay for Human Interferon.** (Eng) Salzberg, S. (Dept. Life Science, Bar-Ilan Univ., Ramat Gan, Israel); Heller, A.; Aboud, M.; Gurari-Rotman, D.; Revel, M. *Virology* 93(1): 209-214; 1979.

Human RD-114 cells chronically infected with a feline RNA tumor virus were treated with 20 or 60 units/ml of human interferon (IF) to determine the kinetics of development of the antiviral state in these cells. The amount of virus released was monitored by reverse transcriptase (RT) activity in the culture medium. RT activity was inhibited by 70%-80% 4-6 hr after the cells were treated with 60 units/ml IF. When RD-114 cells were treated with 20 or 60 units/ml IF for 18 hr, the antiviral state remained unaltered at 20 hr after IF removal; with the higher concentration, >70% inhibition in virus release was observed 24 hr postremoval. Human IF and mouse IF showed species specificity when tested for their effects on virus release from RD-114 and mouse NIH/3T3 (murine leukemia virus)

cells. Human IF was titrated on RD-114 cells by monitoring the RT activity in the culture medium or by determining the reduction in the number of plaques formed on cell monolayers after infection with vesicular stomatitis virus. Both assays were identical in their sensitivity. The use of the RT assay for detecting human fibroblast IF during its purification by ion-exchange chromatography is illustrated. (18 refs)

79-2748 Feline Oncornavirus-associated Cell-Membrane Antigen (FOCMA) (Meeting Abstract). (Eng) Neil, J. C. (Dept. Veterinary Pathology, Univ. Glasgow Veterinary Sch., Bearsden Road, Bearsden, Glasgow, Scotland) *Br J Cancer* 39(4): 471-472; 1979 (no refs)

79-2749 Translation of Bovine Leukemia Virus Virion RNAs in Heterologous Protein-synthesizing Systems. (Eng) Ghysdael, J. (Departement de Biologie Moleculaire, Universite Libre de Bruxelles, 1640 Rhode St. Genese, Brussels, Belgium); Kettmann, R.; Burny, A. *J Virol* 29(3): 1087-1098; 1979.

Studies were conducted to define the bovine leukemia virus (BLV) genome more precisely and to identify the genetic information encoded in it. BLV 60S-70S RNA was heat-denatured, the polyadenylic acid-containing species were separated by velocity sedimentation, and several size classes were translated in a micrococcal nuclease-treated cell-free system from rabbit reticulocytes. The major RNA species sedimented at 38S and migrated as a single component of mol wt 2.95×10^6 when analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The predominant polypeptides of the in vitro translation of BLV virus 38S RNA were products with mol wts of 70,000 and 45,000; minor components with mol wts of 145,000 and 18,000 were also observed. Two lines of evidence indicate that the 70,000- and 45,000-mol wt polypeptides represent translation products of the *gag* gene of the BLV genome (Pr70*gag* and Pr45*gag*). First, they are specifically precipitated by a monospecific antiserum to the major internal protein, p24; second, they are synthesized and correctly processed into virion proteins p24, p15, and p10 in *Xenopus laevis* oocytes microinjected with BLV virus 38S RNA. The 145,000-mol wt polypeptide was immunoprecipitated by the anti-p24 serum and not by an antiserum to the major envelope glycoprotein, gp60. It contained all the tryptic peptides of Pr70*gag* and additional peptides unique to it and, thus, represents an elongation product of Pr70*gag* in an adjacent gene, presumably the *pol* gene. The 18,000-mol wt product was antigenically unrelated to p24 and gp60 and shared no peptides in common with Pr70*gag*, Pr45*gag*, or the 145,000-mol wt polypeptide. It was maximally synthesized on a polyadenylic acid-containing virion 16S-18S RNA, and

evidence that this RNA is a 3' end-derived subgenomic fragment of the BLV genome rather than a contaminating cellular RNA is presented. (36 refs)

79-2750 Carnivores Have Sequences in Their Cellular DNA Distantly Related to the Primate Endogenous Virus, MAC-1. (Eng) Bonner, T. I. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD 20014); Todaro, G. J. *Virology* 94(1): 224-227; 1979.

The hybridization of the complementary DNA (cDNA) of a new endogenous primate virus (MAC-1) isolated from a *Macaca arctoides* cell line to the DNA's of several feline species and other carnivores was assayed using low-stringency-hydroxyapatite conditions. At 60 C, the amount of hybrid was 2.1%-4.3% for two primate species (human and howler monkey) and the dog, compared with 10.0%-15.7% for the feloid carnivores. In addition, the melting temperature for the hybrids that formed with the feloid carnivore DNA's ranged from 58 to 61 C, compared with 56 C for those formed with the primate DNA's. The kinetics of hybridization of MAC-1 cDNA with two representative carnivores indicated that there would be at least 50 copies of viral gene sequences per haploid genome. In summary, cDNA transcripts from the endogenous macaque virus detect related sequences in carnivores that, from the S_1 nuclease values, must be distinct from the two known cat C-type viruses, RD-114 and feline leukemia virus. These sequences appear to be present in a number of carnivores, indicating that they have been present for several million years. Similarly, MAC-1-related sequences have been previously concluded to be present in primates for at least 40 million years. (13 refs)

79-2751 Primate Retroviruses: Intracistronic Mapping of Type D Viral *gag* Gene by Use of Nonconditional Replication Mutants. (Eng) Devare, S. G. (Viral Genetics Section, Lab. Cellular and Molecular Biology, NCI, Bethesda, MD 20014); Stephenson, J. R. *J Virol* 29(3): 1035-1043; 1979.

Findings that represent the first determination of the *gag* gene order of an endogenous retrovirus of primate origin and provide information regarding the evolutionary relatedness of C- and D-type mammalian retroviruses are presented. Nonconditional replication mutants of squirrel monkey retrovirus (SMRV), an endogenous D-type virus of primates, are defective in posttranslational processing of nonglycosylated virus-coded structural proteins. Utilizing these mutants, in combination with sensitive radioimmunological assays, the existence of a 72,000-dalton precursor polypeptide (Pr72*gag*) encoded by a region of the SMRV genome designated *gag* was demonstrated. Posttranslational cleavage of this precursor polypeptide gives rise to virion structural proteins with mol wts of 35,000

(p35), 16,000 (p16), 12,000 (p12), and 9,000 (p9) daltons. p35, p16, and p9 are phosphorylated. Analysis of viral antigen expression in cell lines nonproductively infected with either of two replication-defective SMRV mutants or mink cells productively infected with wild-type SMRV resulted in the detection of several SMRV Pr72gag intermediate cleavage products. Adjacent proteins within such intermediates were identified by specific competition immunoassays, and the intracistronic order of individual structural proteins with SMRV Pr72gag was tentatively deduced as NH₂-p16-p12-p35-p9-COOH. 79-2752 Herpesvirus saimiri: Studies In Vivo and In Vitro with Attenuated and Oncogenic Strains (Meeting Abstract). (Eng) Wright, J. J. (Univ. Illinois, Medical Center, Urbana, IL 61801) *Diss Abstr Int [B]* 39(10): 4748; 1979 (no refs)

79-2753 Structure and Origin of Defective Genomes Contained in Serially Passaged Herpes Simplex Virus Type 1 (Justin). (Eng) Locker, H. (Dept. Biology, Univ. Chicago, Chicago, IL 60637); Frenkel, N. *J Virol* 29(3): 1065-1077; 1979.

Studies concerning the evolution and structural organization of the defective herpes simplex virus type 1 (HSV-1, Justin) genomes are reported, along with the precise localization of the small (S)-component sequences from which these defective genomes arise. Restriction enzyme and hybridization analyses revealed that high-density DNA prepared from passage 15 of serially passaged HSV-1 contains three major classes of modified viral DNA molecules, each composed of distinct but closely related types of repeat units. The DNA sequences within the three types of repeat units are colinear with the DNA sequences located at the right end (between coordinates 0.94 and 1.0) of the parental HSV-1 genome. Thus, the three types of repeat units each contain the entire repeat sequence (*ac*) which brackets the unique sequences of the S component of HSV-1 DNA and differ only with respect to the amount of unique S sequences that they contain. The three classes of high-density DNA molecules were stably propagated between passages 6 and 15 of this series. (31 refs)

79-2754 Kinetics of Nuclear Changes During Herpetic Infection of Human Primary Liver Cell Cultures. (Eng) Scotto, J. M. (Unite de Recherches d'Hepatologie Infantile, U 56 INSERM, Hopital d'Enfants, F-94270 Le Kremlin-Bicetre, Paris Cedex 06, France); Sauron, B.; Dupuy-Coin, A. M.; Gautier, M. *J Submicrosc Cytol* 11(2): 229-241; 1979.

The kinetics of herpes simplex virus type 2 (HSV-2)-

induced nuclear changes in human primary liver cell cultures infected at high multiplicity (100-200 plaque-forming units/cell) was investigated electron microscopically. During the first 4 hr of infection, the nucleoli were progressively and completely destroyed. Between 5 and 8 hr, the chromatin lost its initial condensed appearance. During the course of infection, a central electron-lucent area appeared in the nuclei that, between 5 and 8 hr, was seen in almost all nuclei. The number of hairy dense bodies and plexiform structures increased during viral replication. These observations indicate that primary cultures of human liver cells behave in a manner similar to that of other cells when infected with HSV-2. (49 refs)

79-2755 Herpes Simplex Virus Types 1 and 2: Comparison of the Defective Genomes and Virus-specific Polypeptides. (Eng) Bookout, J. (Dept. Virology and Epidemiology, Baylor Coll. Medicine, Houston, TX 77030); Hirsch, I.; Purifoy, D. J.; Biswal, N. *Virology* 93(2): 598-604; 1979.

The defective DNA's of herpes simplex virus (HSV) types 1 and 2 were investigated with regard to their reassociation kinetics and susceptibility to cleavage by *HindIII*, the polypeptides synthesized after infection with serially passaged HSV-1 or HSV-2 were studied. Defective DNA of types 1 and 2 showed similar reassociation kinetics with a complexity of approx 12.43×10^6 daltons. This estimate suggests that the defective genomes have a complexity less than 13.4% of the standard genome. The defective DNA's appeared to be homologous to 12.1 or 8.5% of the standard genome. The percent homology between defective DNA's of types 1 and 2 was estimated at 40%. An overproduction of an early polypeptide, VP175, was observed in cells infected with defective HSV-1, but no overproduction of any polypeptide equivalent to VP175 was seen in cells infected with defective HSV-2. The results suggest that although the defective DNA's of HSV-1 and HSV-2 have some common physiochemical properties, their base sequences and genomic expression in the infected cell are different. (23 refs)

79-2756 Herpes Simplex Virus DNA Isolation from Infected Cells with a Novel Procedure. (Eng) Pignatti, P. F. (Istituto di Genetica, Laboratorio di Genetica Biochimica, Pavia, Italy); Cassal, E.; Meneguzzi, G.; Chenciner, N.; Milanesi, G. *Virology* 93(1): 260-264; 1979.

Herpes simplex virus type 1-infected Hep₂ cells were extracted in the presence of 0.25% Triton X-100-0.2 M NaCl. Viral DNA associated with proteins was found in the supernatant after low-speed centrifugation. Only viral DNA was recovered by this procedure, as shown by CsCl density analysis after deproteinization. Full-length viral DNA

molecules were observed in the electron microscope. (10 refs)

- 79-2757 Herpes Simplex Virus (HSV) in C-1300 Mouse Neuroblastoma Cells (Meeting Abstract). (Eng) Schwartz, J. (Mt. Sinai Sch. Medicine, New York, NY); Elizan, T. S. *J Neuropathol Exp Neurol* 38(3): 339; 1979 (no refs)

- 79-2758 Membrane Proteins Specified by Herpes Simplex Viruses. IV. Conformation of the Virion Glycoprotein Designated VP7(B₂). (Eng) Sarmiento, M. (Dept. Pathology, Univ. Chicago, Chicago, IL 60637); Spear, P. G. *J Virol* 29(3): 1159-1167; 1979.

The physical properties of detergent-solubilized herpes simplex virus type 1 envelope proteins were investigated, and the structure of the virion glycoprotein designated VP7(B₂) was partially characterized. VP7(B₂) was extracted from virions by a nonionic detergent in the form of an oligomer, whereas the other detergent-soluble envelope proteins were extracted as monomers. The subunits of the VP7(B₂) oligomer were resistant to dissociation by 2-mercaptoethanol or by a mixture of sodium dodecyl sulfate (SDS) and 2-mercaptoethanol except at elevated temperature. The oligomeric form of solubilized VP7(B₂) was predominantly dimeric, based on the sedimentation rates in sucrose gradients and the electrophoretic mobilities in SDS-containing acrylamide gels of the undissociated and heat-dissociated forms of VP7(B₂). It is concluded that the oligomeric conformation of solubilized VP7(B₂) is maintained at least in part by noncovalent interactions and that the oligomer is apparently composed of two polypeptides with similar electrophoretic mobility, perhaps of two identical glycopolypeptides. (35 refs)

- 79-2759 Membrane Proteins Specified by Herpes Simplex Viruses. III. Role of Glycoprotein VP7(B₂) in Virion Infectivity. (Eng) Sarmiento, M. (Dept. Pathology, Univ. Chicago, Chicago, IL 60637); Haffey, M.; Spear, P. G. *J Virol* 29(3): 1149-1158; 1979.

A temperature-sensitive (ts) mutant of herpes simplex virus type 1 (HSV-1) that has a selective defect in the accumulation of envelope glycoprotein VP7(B₂) at the nonpermissive temperature was used to investigate the role of VP7(B₂) in virion infectivity. At the nonpermissive temperature, the mutant produced virions that have very low specific infectivity. Upon sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis, a fraction of the VP7(B₂) from the parental wild-type HSV-1 was present as an SDS-stable dimer, whereas this form of VP7(B₂) was not detected in the mutant virions. The infectivity of ts HSV-1 virions pro-

duced at 34 C was inactivated by heat at a much higher rate than that of the parental HSV-1. Kinetics studies indicated that the ratio of the binding efficiencies of ts HSV-1 produced at 34 C and that produced at 39 C (to Vero cells) was 1.3:1 after 30 min of incubation but 2:1 after 2 hr. However, it is unlikely that this difference in adsorption could account for the large differences in specific infectivities. Treatment with polyethylene glycol, which promotes membrane fusion, enhanced the infectivity of mutant virions produced at 39 C by as much as 80-fold but had no effect on virions produced at 34 C or on parental HSV-1 infectivity. These findings indicate that the poor infectivity of the mutant virions is caused by failure to penetrate the host cell rather than by failure to absorb. It is concluded that VP7(B₂) is required for the penetration stage of the infective process following adsorption. (31 refs)

- 79-2760 Transcription of Herpes Simplex Virus Type 1 DNA by Eukaryotic and Prokaryotic RNA Polymerases: Size and Sequence Analysis of RNA. (Eng) Chenciner, N. (Centre de Biochimie, Faculte des Sciences, 06034 Nice, France); Meneguzzi, G.; Cassai, E.; Milanese, G. *Virology* 94(1): 232-236; 1979.

The transcription of herpes simplex virus type 1 (HSV-1) DNA by purified RNA polymerase was analyzed in vitro, to determine if the simple interaction of these two elements could reproduce the transcription observed immediately after HSV-1 infection. HSV-1 DNA was transcribed in vitro by *Escherichia coli* RNA polymerase and by calf thymus RNA polymerase B. The RNA's obtained were 45%-50% self-complementary and had broad size distributions. The prokaryotic enzyme failed to transcribe the inverted repeats of the small component of the molecule. Small, unique regions of the large component were preferentially transcribed with this RNA polymerase. In contrast, all regions were uniformly transcribed by the eukaryotic enzyme. An approx distribution of initiation sites for both polymerases was determined. (23 refs)

- 79-2761 Cell Surface Glycoprotein Changes in Epstein-Barr Virus-Positive and -Negative Human Hematopoietic Cell Lines. (Eng) van Beek, W. P. (Div. Cell Biology, Anton van Leeuwenhoek Huis, Netherlands Cancer Inst., Amsterdam, Netherlands); Nilsson, K.; Klein, G.; Emmelot, P. *Int J Cancer* 23(4): 464-473; 1979.

Epstein-Barr virus (EBV)-positive and -negative human hematopoietic cell lines were studied with regard to their cell-surface glycopeptides. Fast-eluting glycopeptides were demonstrated by gel filtration analysis in 2 EBV-negative and 14 EBV-positive Burkitt's lymphoma (BL) cell lines, 14/15 EBV-negative lymphoblastoid cell lines, 5 non-BL lines, and 5/6 leukemia lines. One lymphoblastoid line derived from a patient with infectious mononucleosis, B

lymphoblasts stimulated by pokeweed mitogen, one leukemia line, and two myeloma lines did not contain the fast-eluting material. The BL lines were relatively insensitive to neuraminidase digestion and mild acid treatment, as were the lymphoblastoid cell lines. The non-BL, leukemia, and myeloma cell lines were sensitive to neuraminidase digestion. In general, the glycopeptide elution profiles of the lymphoblastoid lines were strikingly similar to those of the BL lines. The data support the hypothesis that BL develops from the stepwise malignant transformation of an EBV-infected population of B cells. (63 refs)

- 79-2762** Induction of the Epstein-Barr Virus (EBV) Cycle in Latently Infected Cells by n-Butyrate. (Eng) Luka, J. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Kallin, B.; Klein, G. *Virology* 94(1): 228-231; 1979.

A dramatic increase in the number of virus-producer cells following treatment of the prototype Epstein-Barr virus (EBV)-carrying P3HR-1 and B95-8 lines with n-butyrate is reported. This compound was tested in view of its ability to induce differentiation in the Friend erythroleukemia system and to inhibit DNA synthesis. Induction was also seen in the nonproducer Raji and the low-producer Daudi lines, but at a much lower level. The virus-containing supernatant of the butyrate-treated P3HR-1 cells induced Epstein-Barr nuclear antigen preferentially in EBV-negative Ramos target cells, whereas the spontaneously produced virus induced predominantly EA in Raji indicator cells. This suggests a possible difference in the biological properties of the butyrate-induced vs the prototype virus. In addition to providing a convenient method to obtain a high yield of viral DNA and virus antigen-producing cells in the EBV system, these studies raise interesting questions concerning the mechanism of EBV induction and its possible relationship to the known differentiation inducing ability of n-butyrate. (24 refs)

- 79-2763** Interaction Between Epstein-Barr Virus and Type-C Virus in Human Cells. (Eng) Osato, T. (Dept. Virology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Sapporo 060, Japan); Yamamoto, K.; Matsuo, T.; Aya, T.; Mizuno, F.; Nonoyama, M. *IARC Sci Publ* 20: 413-420; 1978.

The interaction between Epstein-Barr virus (EBV) and C-type virus in human lymphoid FVNC cells was studied to determine the significance of possible cofactor(s) influencing EBV oncogenesis. The FVNC cell line was established by exposing EBV genome-positive human lymphoid NC-37 cells to C-type Friend murine leukemia virus. Each FVNC cell contains a few EBV genomes and a C-type viral genome in repressed form. Compared with NC-37 cells,

FVNC cells showed three to four times more early antigen (EA)-positive cells after superinfection with EBV. C-type viral induction was also observed in FVNC cells following EBV superinfection. When FVNC cells were exposed to C-type virus, a high frequency of induction of EBV-related early nuclear antigen was demonstrated. The results of human-mouse somatic cell hybridization experiments suggested that the repressed EBV and C-type viral genomes may be associated with different chromosomes in FVNC human lymphoid cells. (5 refs)

- 79-2764** Early and Late Components of Epstein-Barr Virus-associated Membrane Antigen in Superinfected Daudi Cells and Their Reactivity with Sera from Nasopharyngeal Carcinoma Patients. (Eng) Hinuma, Y. (Dept. Microbiology, Kumamoto Univ. Medical Sch., Kumamoto, Japan); Sairenji, T.; Maeda, M. *IARC Sci Publ* 20: 385-390; 1978.

An indirect membrane immunofluorescence technique was used to study the appearance of early and late membrane antigen (MA) following superinfection of Daudi cells with the P3HR-1 strain of Epstein-Barr virus (EBV). The levels of MA, early antigen (EA), and viral capsid antigen (VCA) increased by 64%, 34%, and 23%, respectively, 22 hr after infection. Puromycin (25 µg/ml) inhibited MA, EA, and VCA synthesis, and cytosine arabinoside (ara-C, 20 µg/ml) or disodium phosphoacetate (200 µg/ml) inhibited the synthesis of MA and VCA, but not EA. Differential absorption of an EBV antibody-positive human serum with ara-C-treated or -untreated infected cells revealed two antigenically different components of MA: early MA (ara-C-insensitive) and late MA (ara-C-sensitive). Three of five sera from patients with nasopharyngeal carcinoma, but none of five sera from normal adult humans, showed an apparent "prozone" phenomenon in their reactivity against late MA, but not early MA. (9 refs)

- 79-2765** Polyclonal Immunoglobulin Secretion by Human B Lymphocytes Exposed to Epstein-Barr Virus In Vitro. (Eng) Kirchner, H. (Inst. Virus Res., German Cancer Res. Center, 69 Heidelberg, W. Germany); Tosato, G.; Blaese, R. M.; Broder, S.; Magrath, I. T. *J Immunol* 122(4): 1310-1313; 1979.

The Epstein-Barr virus (EBV)-induced activation of human peripheral blood lymphocytes was studied by a reverse hemolytic plaque assay for the detection of Ig-producing cells, and the results were compared with the effects of pokeweed mitogen (PMW) on these cells. Both agents caused the development of Ig-producing cells in cultures of unseparated mononuclear cells. However, B-cell populations sufficiently depleted of T cells by a variety of techniques to be unresponsive to PMW showed a marked response to EBV. The reactivity of B cells to PWM could

be restored by irradiated T cells, whereas there was no effect of irradiated T-cells on the reactivity to EBV. These data suggest that the response to EBV, in contrast to the PWM response, is T-cell-independent. Lymphocytes secreting each class of Ig (IgG, IgA, and IgM) were found in EBV-stimulated cultures of both unseparated mononuclear cells and T-cell-depleted cultures, demonstrating that the response in each Ig class is also T-cell-independent in this system. When unseparated cell populations and B-cell populations cultured at the same cell concentration were compared, the latter showed a two- to fivefold increased reactivity to EBV. This difference appeared to be caused primarily by an enrichment of B-cells, as was suggested by experiments in which the two cell populations were compared at different cell concentrations. - 79-2766 Epstein-Barr Virus-related Antibody Patterns in Ataxia-Telangiectasia.** (Eng) Berkel, A. I. (Immunology Lab., Hacettepe Children's Hosp., Ankara, Turkey); Henle, W.; Henle, G.; Klein, G.; Ersoy, F.; Sanal, O. *Clin Exp Immunol* 35(2): 196-201; 1979.

Since Epstein Barr virus (EBV) has oncogenic potential and high titers of EBV-related antibodies are found in patients with decreased cellular immunity, these titers were determined in 27 patients with ataxia-telangiectasia (AT) and twenty-two healthy members of their families, 22 patients with other diseases (including 10 with Behcet's disease and 10 with various primary immune deficiencies) and 15 healthy members of their families, and 23 unrelated healthy controls. The AT patients showed an increased incidence (55.6%) of high antibody titers ($\geq 1:320$) to viral capsid antigen (VCA) and a high incidence (48.2%) of antibodies to EBV-induced early antigens (EA: ranging in titer from 1:10 to 1:60), but low titers ($< 1:10$) of antibodies to EBV-associated nuclear antigen (EBNA) in 44.2% of the cases. The geometric means of anti-VCA were three- to fourfold higher and those of anti-EBNA sixfold lower than the values for the control groups. The values for patients with the other diseases did not differ significantly from control values except for a higher incidence of anti-EBNA titers of $< 1:10$ (38.1%, vs 4%-5%). AT patients with low anti-EBNA titers tended to have more advanced T-cell deficiencies than AT patients with moderate anti-EBNA titers, as detected by counts of total lymphocytes and erythrocyte-rosetting cells and by skin test responses. The results support the hypothesis that a functioning T-cell system is required to release EBNA from EBV genome-carrying cells for initial and maintained production of anti-EBNA. (17 refs)

- 79-2767 Identification of the Soluble HVP-associated Antigen of the Lymphoblastoid Cell Line Established from Lymphomatous Baboon (*Papio***

***hamadryas*).** (Eng) Voevodin, A. F. (Lab. Experimental Oncology, Inst. Experimental Pathology and Therapy, USSR Acad. Medical Sciences, Sukhumi, USSR); Lapin, B. A.; Agrba, V. Z.; Timanovskaya, V. V. *Acta Biol Med Ger* 37(9): 1509-1512; 1978.

A new, indirect, double-immunodiffusion technique for the detection of Epstein-Barr virus (EBV)-associated antigen and antibody is described, and it was used to identify the soluble lymphomatous baboon herpesvirus (HVP)-associated antigen. The technique involves three steps: (1) simple double immunodiffusion with extracts of Raji cells (or other EBV genome-positive cells) and human sera containing antibodies against EBV-associated soluble antigen; (2) extensive washing and treatment of the preparations with anti-human globulin; and (3) extensive washing and tannic acid treatment. With this technique, the soluble HVP-associated antigen from a lymphoblastoid cell line established from lymphomatous baboon (KMPG-1) was shown to be indistinguishable from the soluble EBV-associated antigen. - 79-2770 Transplantation of Polyoma Virus-infected Bovine Odontogenic Tissues (Meeting Abstract).** (Eng) Chalk, A. J. (Dept. Dental Medicine and Surgery, Univ. Melbourne, Melbourne, Australia) *J Dent Res* 58(Special C): 1208; 1979 (1 ref)

- 79-2771 Multiple Forms of Polyoma Virus Tumor Antigens from Infected and Transformed Cells.** (Eng) Simmons, D. T. (Sch. Life and Health Sciences, Univ. Delaware, Newark, DE 19711); Chang, C.; Martin, M. A. *J Virol* 29(3): 881-887; 1979.

The relationship between the multiple forms of polyoma (Py) virus tumor antigens from infected and transformed

cells was examined by analyzing their methionine-containing tryptic peptides. At least three distinct forms of Py virus tumor antigens were isolated from productively infected and transformed hamster cells by immunoprecipitation with serum directed against Py-induced tumors (anti-T serum). Their proteins had approx mol wts of 105,000 (large T antigen), 63,000 (middle T antigen), and 20,000 (small T antigen), as estimated by acrylamide gel electrophoresis. An examination of the appearance of these antigens in Py-infected mouse cells showed that all three polypeptides were synthesized maximally at approx the same time after infection. Analysis of the methionine-containing tryptic peptides of these proteins indicated that the large, middle, and small forms of polyoma T antigens contained five similar or identical peptides. In addition, the 63,000- and 20,000-dalton antigens contained two other methionine peptides absent from the large T-antigen species. Other methionine peptides were found only in the large or middle T-antigen forms. These and previous results suggest that the three T-antigen species have the same NH₂-terminal end regions but different COOH termini. A model describing the synthesis of these polypeptides from different regions of the Py virus genome is presented. (22 refs)

- 79-2772 Biological Activity of Polyoma Viral DNA in Mice and Hamsters.** (Eng) Israel, M. A. (Lab. Biology Viruses, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD 20014); Chan, H. W.; Hourihan, S. L.; Rowe, W. P.; Martin, M. A. *J Virol* 29(3): 990-996; 1979.

The biological activity of polyoma (Py) viral DNA was evaluated by studying its ability to initiate productive infection in weanling mice, as measured by the MAP (mouse antibody production) test, and to induce tumors in newborn hamsters. Viral DNA administered parenterally was 4-5 logs less efficient than Py virions in establishing infection in mice. Supercoiled viral DNA was infectious for mice after parenteral administration, giving mean infective doses of 10^{-3} to 10^{-4} μ g. However, animals fed microgram quantities of Py DNA I did not become infected. The relaxed, circular form of viral DNA (DNA II) was nearly as infectious as the supercoiled form, whereas full-length linear forms (DNA I cleaved with the single-cut restriction endonuclease R.*Bam*HI or R.*Eco*RI) retained 15%-25% of the infectivity determined for DNA I. Approx 10% of newborn hamsters inoculated ip with 0.5 μ g of Py DNA I developed tumors. In contrast, the same amount of viral DNA that had been cleaved in the early region with R.*Eco*RI induced tumors in 43%-50% of inoculated hamsters. The tumors observed after ip administration of Py DNA were all in the abdominal wall near the site of injection. These studies indicate that the efficiency of infection of mice by Py DNA is adequate to allow the use of mice as a model system in experiments requiring the expres-

sion of the Py genome, particularly in studies of recombinant DNA molecules. (37 refs)

- 79-2773 Early Events in the Infection of Permissive Cells with Polyoma Virus: Comparison of Chymotrypsin-treated and Untreated Virus.** (Eng) Chlumecka, V. (Dept. Biochemistry, Univ. Alberta, Edmonton, Alberta T6G 2H7, Canada); D'Obrenan, P.; Colter, J. S. *Virology* 94(1): 219-223; 1979.

Polyoma (Py) virus exposed to chymotrypsin during purification (chymo+ virions) and Py virus purified without exposure to the protease (chymo- virions) were examined with respect to the early events of the infectious cycle. In addition, the abilities of chymo+ and chymo- virions to stimulate the synthesis of cellular and viral DNA were compared, as were the infectivities of DNA's isolated from the two preparations. Exposure to the protease had no effect on the ability of the virions to attach to, penetrate into, and enter the nuclei of mouse embryo fibroblasts. Uncoating, which was concluded to take place exclusively in the nuclei, appeared to be somewhat delayed in the case of the chymo+ virions. The only identifiable product of uncoating was a DNA protein complex having a sedimentation coefficient of the order of 52S-55S. Stimulation of cellular and viral DNA synthesis was greatly reduced in cells infected with chymo+ virions relative to those infected with chymo- virions, but the specific infectivities of DNA's isolated from chymo+ and chymo- virions were precisely the same. (14 refs)

- 79-2774 DNA Sequence Alterations in Hr-t Deletion Mutants of Polyoma Virus.** (Eng) Hattori, J. (Dept. Pediatrics, Sidney Farber Cancer Inst., 44 Binney St., Boston, MA 02115); Carmichael, G. G.; Benjamin, T. L. *Cell* 16(3): 505-513; 1979.

The DNA sequence alterations in several host range- and transformation-defective (hr-t) mutants of polyoma virus were investigated. These mutants are defective in one of the two known viral functions essential for transformation, and they are altered with respect to several minor tumor (T) antigen species. The lesions in some of these mutants have been mapped previously by marker rescue experiments to Hpa II fragment 4 (Hpa II-4, 78.4-91.7 map units) in the proximal part of the early region of the viral DNA. Thirteen of sixteen hr-t mutants examined carry deletions 2 to 5 map units [100-250 base pair (bp)] long in Hpa II-4. Three mutants carry either point mutations or very small deletions/insertions. Eight of the deletion mutants were mapped closely with restriction enzymes. Seven of them have deletions located entirely within the Hae III subfragment A of Hpa II-4 (the Hae A subfragment, 78.4-85.2 map units), and one extends just beyond this subfragment, ending at 85.5 map units. The complete sequence of the wild-type

Hae A subfragment was determined and compared with those of four deletion mutants, NG-18, A-8, 6B-5, and B-2. The deletion in each of these mutants is out of phase: NG-18, 187 bp; A-8, 127 bp; 6B-5, 179 bp; B-2, 241 bp. All are expected to remove protein sequences in the C terminal part of the small t antigen. (42 refs)

- 79-2775 Restriction Endonuclease Cleavage Map of the DNA of JC Virus.** (Eng) Martin, J. D. (Dept. Medical Microbiology, Univ. Wisconsin Medical Sch., Madison, WI 53706); Frisque, R. J.; Padgett, B. L.; Walker, D. L. *J Virol* 29(3): 846-855; 1979.

A restriction endonuclease cleavage map of the DNA of JC virus (JCV), the human polyomavirus associated with progressive multifocal leukoencephalopathy, was derived. The following endonucleases were used: *EcoRI*, *HpaI*, and *PstI* (1 cleavage site each); *HindII* (4 sites); and *HindIII* (3 sites). Map position 0 was arbitrarily assigned to the *EcoRI* site, and the other cleavage sites were ordered with respect to it. The *PstI* site was placed at map position 0.315 and the *HpaI* site at 0.850. The four *HindII* sites were placed at map positions, 0.145, 0.355, 0.855, and 0.975, the three *HindIII* sites at map coordinates 0.550, 0.630, and 0.670. By agarose gel electrophoresis of fragmented DNA, the size of full-length DNA of JCV was estimated to be $5,125 \pm 105$ base pairs (98% \pm 2% of the length of simian virus 40 DNA). (24 refs)

- 79-2776 Persistent BK Papovavirus Infection of Transformed Human Fetal Brain Cells. I. Episomal Viral DNA in Cloned Lines Deficient in T-Antigen Expression.** (Eng) Takemoto, K. K. (Lab. Viral Diseases, Natl. Inst. Allergy and Infectious Diseases, Bethesda, MD 20014); Linke, H.; Miyamura, T.; Fareed, G. C. *J Virol* 29(3): 1177-1185; 1979.

Data relevant to two different virus-cell interactions, persistent infection and cellular transformation, are presented as a result of studies of cultures of human fetal brain (HFB) cells persistently infected with BK human papovavirus (BKV). After infection of permissive HFB cells by BKV, the vast majority of the cells were killed by the virus, but rare survivors were recovered after frequent medium changes. These surviving cells grew and formed visible colonies after 5-6 wk and were thereafter established as permanent cell lines. These cells, designated as BK-HFB cells, were persistently infected and shed BKV. Morphologically, they were small, polygonal cells that had transformed growth properties. Their plating efficiency on solid substrates or in semisolid medium was high, and they were tumorigenic in athymic nude mice. Cloning experiments in medium containing BKV antiserum revealed that BKV did not persist in the cultures in a simple carrier state. All cloned cell lines were initially tumor (T)-antigen

negative and virus-free. However, every clone began to release BKV and again became persistently infected within 3 wk after removal of BKV antiserum. After rigorous antibody treatment, 4/7 clones still released virus spontaneously upon removal of antiserum; three clones have remained virus-free and are apparently cured. Although these cloned cell lines are T- and V-antigen negative when grown in antiserum-containing medium, they retain "free" or episomal BKV genomes; integrated viral DNA was not detected in any of the clones. These free genomes are indistinguishable from prototype BKV DNA and are found in much larger amounts in virus-shedding cell lines. (34 refs)

- 79-2777 Mapping and Ordering of Fragments of BK Virus DNA Produced by Restriction Endonucleases.** (Eng) Freund, J. (Dept. Clinical Microbiology, Univ. Chicago, Chicago, IL 60637); di Mayorca, G.; Subramanian, K. N. *J Virol* 29(3): 915-925; 1979.

The 51 cleavage sites produced in the DNA of BK virus (BKV), a human papovavirus, by a combination of 10 different restriction endonucleases are described. These sites were mapped and ordered relative to one another as well as to the five fragments generated previously by the digestion of BKV with *HindIII* and *EcoRI*. One of the enzymes used in this study, *HaeIII*, recognizes the sequence GGCC (guanine-guanine-cytosine-cytosine), which is present within the genome of BKV 21 times. A large percentage of these sites are within the late region of the BKV genome, a situation similar to that in the simian virus 40 genome. The cleavage map produced by the 10 restriction endonucleases is being used to construct and characterize deletion mutations and to map the integration sites on the viral DNA of BKV-transformed cells. (32 refs)

- 79-2778 BK Virus DNA Sequence: Extent of Homology with Simian Virus 40 DNA.** (Eng) Yang, R. C. (Section Biochemistry, Molecular and Cell Biology, Cornell Univ., Ithaca, NY 14853); Wu, R. *Proc Natl Acad Sci USA* 76(3): 1179-1183; 1979.

The primary nucleotide sequence of three regions of BK virus (BKV) variant (MM) DNA was determined by direct DNA sequence analysis. The region between map positions 0.715 and 0.900 included the initiation points and partial coding sequences of the putative VP2 and VP3 proteins of BKV(MM), the amino acid sequences of which showed >80% homology with those of VP2 and VP3 of simian virus 40 (SV40). The sequence of a potential leader protein (protein X), 66 amino acids long for BKV(MM) and 62 long for SV40, is also deduced. The regions between 0.595 and 0.398 and 0.310 and 0.175 included the coding sequence for the entire small tumor (t) antigen and most of

the large T antigen of BKV(MM). The DNA sequence within these regions comprised >50% of the complete BKV(MM) genome and showed a 70% sequence homology with the corresponding regions of SV40 DNA. This high degree of homology is at variance with the reported homology values of 11%-20% estimated by hybridization measurements of heteroduplex analyses. Possible explanations for the discrepancies are presented. (20 refs)

- 79-2779 Transcription of the Cellular DNA Sequences in a Cloned Host-substituted SV40 DNA Variant.** (Eng) Hartman, J. R. (Dept. Virology, Weizmann Inst. Science, Rehovot, Israel); Laub, O.; Aloni, Y.; Winocour, E. *Virology* 94(1): 82-94; 1979.

The transcription of a cloned host-substituted simian virus (SV40) genome of defined structure was studied in BSC-1 monkey cells coinfecting with wild-type virus and in *in vitro* reactions with Sarkosyl nuclear extracts (transcription complex preparations) of the coinfecting cells. Evidence for the transcription of monkey DNA sequences in substituted SV40 was obtained in both systems. Efforts to detect similar transcripts in uninfected cells or in cells infected with wild-type SV40 alone were not successful. Both the highly reiterated and nonreiterated types of cellular DNA sequences (which are linked in the genome of the cloned substituted SV40 variant) were transcribed in the coinfecting cells, and the RNA transcripts were detected in the nuclear and cytoplasmic fractions. Relative to the amount of wild-type SV40 RNA, 40% of the RNA synthesized after *in vitro* incubation of transcription complex preparations hybridized with substituted SV40 cellular DNA sequences. In contrast, only 15% of the nuclear RNA and 4% of the cytoplasmic RNA from intact cells hybridized with the cellular DNA derived from substituted SV40. The sucrose gradient sedimentation profile of the host-substituted SV40 RNA was uniquely different from and more heterogeneous than that of wild-type SV40 RNA. RNA homologous to the host DNA in the substituted SV40 variant was associated only with lighter (disomal and monosomal) ribosomal fractions. (27 refs)

- 79-2780 Identification of New Polypeptide Species (48-55K) Immunoprecipitable by Antiserum to Purified Large T Antigen and Present in SV40-Infected and -Transformed Cells.** (Eng) Melero, J. A. (Dept. Pathology, New York Univ. Medical Center, 550 First Ave., New York, NY 10016); Stitt, D. T.; Mangel, W. F.; Carroll, R. B. *Virology* 93(2): 466-480; 1979.

Intermediate mol wt antigenic polypeptides were identified by immunoprecipitation and gel electrophoresis in cell lines infected with simian virus 40 (SV40). In each line there was a polypeptide with an apparent mol wt of 94,000 daltons [(94K): large tumor antigen (T Ag)], one with a mol wt of

approx 20K (small T Ag), and several with apparent mol wts between 48K and 55K. With respect to the latter polypeptides, the spectrum differed with cell type. Rabbit anti-T serum was able to immunoprecipitate the large T Ag and 48K bands separately, suggesting that they share antigenic determinants. The new antigens were not breakdown products that originated during the manipulations *in vitro*. Deletion temperature-sensitive mutants of SV40 mapping between 0.54 and 0.59 map units did not affect the appearance or size of the new polypeptide species. The SV40 mutant tsA58 produced a 55K species that was very stable at high and low temperatures, suggesting that the mutation did not affect the new antigen. The results suggest that the 48K-55K species may originate either as host-coded species (perhaps induced by the virus) that share determinants with large T Ag or perhaps as SV40-encoded species sharing only very little of the amino acid sequence of the 94K T Ag. (33 refs)

- 79-2781 T Antigen is Bound to a Host Protein in SV40-transformed Cells.** (Eng) Lane, D. P. (Dept. Zoology, Imperial Coll., London SW7, England); Crawford, L. V. *Nature* 278(5701): 261-263; 1979.

The formation of an oligomeric complex between simian virus (SV40) T antigen and a host protein is reported. When an extract of the SV40-transformed mouse cell line SVA31E7 was immunoprecipitated with a rabbit antiserum against purified T, two polypeptides were specifically immunoprecipitated. The more slowly migrating species had a mol wt of 94,000 and was identical to the T antigen. The faster migrating species had mol wt of 53,000 (53K) and was not detected in SV40 lytically infected monkey cells. These same two polypeptides were also specifically immunoprecipitated by other anti-T sera. The 53K protein separated from T by sodium dodecyl sulfate-gel electrophoresis was no longer precipitated by the rabbit anti-T serum, whereas the T antigen isolated in the same way was still fully reactive. The determinants recognized by the rabbit anti-T serum on T are, therefore, absent from the 53K polypeptide. Its immunoprecipitation from cell extracts by the rabbit serum must occur because it exists in a complex with T. It is postulated that the 53K protein is not virally coded since (1) it is not detectable in lytically infected monkey cells; (2) it shares no detectable antigenic determinants with T, but has its own set of antigenic determinants (immunogenic in syngeneic mice); and (3) DNA sequence and messenger RNA mapping data indicate that it would be difficult for the early region of SV40 to encode a third polypeptide of 53,000 mol wt. (25 refs)

- 79-2782 Experimental Viral Infections of the Inner Ear. II. Simian Virus 40 Induced Tumors of the Temporal Bone.** (Eng) Davis, L. E. (Dept. Neurology, Univ. New Mexico Sch. Medicine, Albuquerque, NM

87131); Nager, G. T.; Johnson, R. T. *Ann Otol Rhinol Laryngol* 88(2,part 1): 198-204; 1979.

The pathological, virological, and serological aspects of tumors of the temporal bone induced by inoculation of newborn Syrian hamsters with simian virus 40 (SV40) are presented. Of the 27 animals that reached weanling age, 23 developed tumors. Four to five months after viral inoculation, 21 hamsters developed undifferentiated sarcomas in the sc space adjacent to the temporal bone. Nine tumors invaded the temporal bone, occasionally extending to the subarachnoid space but not to the inner ear. Choroid plexus papillomas developed in four animals (2 of these animals also had sarcomas), with one tumor demonstrating invasion of the cochlear aqueduct, internal auditory canal, and cochlear modiolus. Cells grown from a sarcoma and a choroid plexus papilloma contained tumor antigen and established that the tumors were SV40-induced. (12 refs)

79-2783 Inability of Antiserum Active in Antibody-dependent Cellular Cytotoxicity and Arming Tests to Protect Against Simian Virus 40 Tumor Cell Challenge. (Eng) Prather, S. O. (Sch. Life Sciences, 319A Manter Hall, Univ. Nebraska, Lincoln, NB 68588); Geller, R. W.; Lausch, R. N. *J Natl Cancer Inst* 62(5): 1273-1277; 1979.

Results of further studies of the interaction of simian virus 40 (SV40) antiserum with hamster lymphoid cells are presented. Preincubation of nonadherent normal spleen, or lymph node cells with (SV40) antiserum from Syrian golden hamsters rendered the cells specifically cytotoxic for SV40-transformed hamster embryo fibroblasts (PARA-7 cells). The capacity of a particular antiserum to "arm" (ie, to be made specifically cytotoxic) was comparable with its ability to mediate antibody-dependent cellular cytotoxicity (ADCC). Experiments were performed to determine if the SV40 antiserum had prophylactic activity. Two hours after passive transfer of serum, cytotoxic effector cells could be demonstrated in the blood, spleen, and mesenteric lymph nodes, and the recipients' sera were active in ADCC tests. Nevertheless, these hosts were not resistant to challenge with small numbers of SV40 tumor cells that were given id or intracardiacally, nor was tumor growth suppressed by the addition of normal lymph node cells to the antiserum-pretreated tumor cell inoculum. Thus, SV40 antiserum, active at high titer in ADCC and arming assays, did not prevent or delay the growth of SV40 tumor isografts. (28 refs)

79-2784 Noncoordinate Expression of SV40-induced Transformation and Tumorigenicity in Mouse Cell Hybrids. (Eng) Howell, N. (Div. Molecular Genetics, Sidney Farber Cancer Inst., 44 Binney St., Boston, MA 02115); Sager, R. *Somatic Cell Genet* 5(1): 129-143; 1979.

The expression of transformation phenotypes and of tumorigenicity was analyzed in a series of somatic mouse cell hybrids formed by the fusion of nontumorigenic BALB/c 3T3 cells and the closely related simian virus 40 (SV40)-transformed SVT2 cells. The study was designed to probe the genetic basis of the multiple phenotypic changes induced by SV40 transformation. These hybrids showed noncoordinate expression of the transformation phenotype. Although they cloned at high efficiency in medium with low serum and expressed the SV40 tumor antigen of the SVT2 parent, the hybrid cells grew poorly without anchorage and exhibited a cell and colony morphology intermediate between that of the parents. Tumorigenicity was assayed quantitatively by sc coinjection into athymic nude mice of serial dilutions of 10^2 to 10^5 hybrid cells with 10^7 lethally irradiated 3T3 cells. The results showed that injection of 10 SVT2 cells was sufficient for tumor formation. In contrast, 100-1,000 times more hybrid cells had to be injected for tumor formation. These and other observations show that most 3T3/SVT2 hybrid cells are not tumorigenic but that each population contains a rare subset of tumorigenic cells. (44 refs)

79-2785 Reversion to Methionine Independence in Simian Virus 40-transformed Human and Malignant Rat Fibroblasts Is Associated with Altered Ploidy and Altered Properties of Transformation. (Eng) Hoffman, R. M. (Genetics Unit, Children's Service, Massachusetts General Hosp., Boston, MA 02114); Jacobsen, S. J.; Erbe, R. W. *Proc Natl Acad Sci USA* 76(3): 1313-1317; 1979.

Many transformed and malignant cells, unlike normal cells, do not grow when methionine (MT) in the growth medium is replaced by its immediate precursor homocysteine. However, rare cells from these populations revert to MT independence. Because MT auxotrophy is found only in transformed and neoplastic cells, experiments were conducted to determine whether MT-independent revertants also become normal with respect to properties associated with transformation. It was found that MT-independent revertants of both human fibroblasts transformed by simian virus (SV40) and malignant rat fibroblasts concomitantly reverted for some of the properties associated with the transformed state. Of the 13 MT-independent revertants described, 5 showed increased anchorage dependence, as reflected by reduced cloning efficiencies in methylcellulose; 8 showed an increased serum requirement for optimal growth; 8 showed decreased cell density in medium containing high serum; and 3 altered their cell morphology significantly. Eight of the 13 had increased chromosome numbers. All lines tested contained immunologically identifiable SV40 tumor antigen. Thus, by selecting for MT independence, it is possible to select for heterogeneous transformation revertants, which indicates that there is a relationship between altered MT metabolism and oncogenic transformation. Therefore, a positive metabolic method to select for transformation revertants

has been developed, and its use has resulted in the selection of human transformation revertants. (20 refs)

- 79-2786 Phospholipid Composition of Substrate Adhesion Sites of Normal, Virus-transformed, and Revertant Murine Cells.** (Eng) Cathcart, M. K. (Dept. Microbiology, Case Western Reserve Univ., Cleveland, OH 44106); Culp, L. A. *Biochemistry* 18(7): 1167-1176; 1979.

Evidence is presented that the phospholipid (PL) composition of the substrate adhesion site (AS) is considerably different from that of the whole cell and surface membrane preparations, that it is enriched in certain PL species, and that it is altered as a result of viral transformation. The PL composition of cell-substratum AS's, obtained after [ethylenebis(oxyethylenetriol)]tetraacetic acid-mediated detachment of cells from the tissue culture substratum, was determined for [32 P]orthophosphate-radiolabeled BALB/c 3T3, simian virus 40-transformed (SVT2), and concanavalin A-selected revertant variant cell lines. All major PL classes were found in the substrate-attached material, but there was an enrichment for specific PL species in this adhesive material compared with whole cell and surface-enriched membranes. The PL composition was remarkably similar for the whole cell and surface-enriched membrane fractions from the three cell lines. However, pronounced differences in the PL composition of the AS's were observed as a result of viral transformation--SVT2 sites were clearly enriched in phosphatidylethanolamine and depleted in phosphatidylcholine compared with the 3T3 sites. This alteration in AS PL's of transformed cells reverted to a 3T3-like value in the adhesive material of revertant cells. The composition of adhesive material of newly attaching cells was also examined to differentiate compositional differences between "footpad" adhesion sites and "footprints", adhesive material pinched off from the posterior of cells as they move across the substratum. Pulse and pulse-chase analyses of the [32 P]PL's revealed some differences in synthesis and turnover rates in the three cell lines; in addition, altered rates of deposition of newly synthesized material into AS's of transformed cells were observed. These data afford further evidence that the cell-substratum AS are highly specialized areas of the cell surface enriched in components that are intricately involved in adhesion. The transformation-dependent changes in AS may help to determine the basis for the altered adhesive properties of transformed cells. (49 refs)

- 79-2787 Ultrastructure of the Cell Coat of Untransformed and Simian Virus 40-transformed Fibroblasts.** (Eng) Dvorak, A. M. (Basic Res. Program, Frederick Cancer Res. Center, Frederick, MD 21701); Roblin, R. O.; Morgan, E. S.; Dvorak, H. F. *J Reticuloendothel Soc* 25(2): 163-177; 1979.

The ultrastructure of cell coats of cultured mouse and hamster fibroblasts and their simian virus 40 (SV40)-transformed counterparts was studied using an osmium potassium ferrocyanide (OPF) technique. Mouse 3T3 fibroblasts had abundant OPF-positive cell coats similar to those previously described on macrophages. By contrast, SV40-transformed 3T3 cells showed little or no OPF-positive material, and none was observed at points of cell contacts. Similar findings were obtained with hamster fibroblasts, except that less OPF-positive cell coat was present on untransformed cells compared with untransformed 3T3 cells. The OPF technique also stained a prominent system of cytoplasmic vesicles and vacuoles that were both open to the cell surface and were found as deep as the nuclear membrane. These dense vesicles were present in all four cell lines studied. They were most prominent in the SV40-transformed hamster cells and could represent a secretory system for placing cell coat materials on the cell surface. A migration inhibition factor-like material was secreted in much greater amounts by virus-transformed cells than by their untransformed counterparts. This material inhibited migration of guinea pig macrophages and reduced their OPF-positive cell coat. The increased production of this material may be responsible for reducing the amount of OPF-positive cell coat of SV40-transformed fibroblasts. (25 refs)

- 79-2788 Regulation of Simian Virus 40 Early and Late Gene Transcription without Viral DNA Replication.** (Eng) Birkenmeier, E. H. (Carnegie Inst., Baltimore, MD 21210); Chiu, N.; Radonovich, M. F.; May, E.; Salzman, N. P. *J Virol* 29(3): 983-989; 1979.

Primary cultures of African green monkey kidney cells were infected with the simian virus 40 (SV40) temperature-sensitive mutant *tsA58* at the nonpermissive temperature of 41 C for 12-20 hr. Under these conditions, a defective T antigen was produced and no viral DNA replication was detected. Viral transcription complexes were extracted from infected nuclei with Sarkosyl and the nascent RNA chains were elongated in vitro. From 60% to 70% of the viral RNA synthesized in vitro hybridized to late gene sequences. In contrast, 80%-90% of the nuclear viral RNA labeled in vivo during a 15-min pulse with 3 H-uridine hybridized to early gene sequences. This suggests that selective degradation of late gene transcripts occurs in vivo. The role of T antigen and viral DNA replication in regulation of SV40 transcription is discussed. (18 refs)

- 79-2789 Methylation and Cleavage Sequences of the *Eco*P1 Restriction-modification Enzyme.** (Eng) Bachi, B. (Biozentrum, Universität Basel, Klingelbergstrasse 70 CH-4056, Basel, Switzerland); Reiser, J.; Pirrotta, V. *J Mol Biol* 128(2):143-163; 1979.

The sites of cleavage and methylation in simian virus 40 (SV40) DNA were mapped and their sequences determined. Incubation of the DNA with *Eco*P1 and S-adenosylmethionine plus ATP resulted in cleavage, whereas methylation was observed in the absence of ATP. The methylation sites were restricted to five relatively small regions that agreed well with the positions estimated for cleavage. A-G-A-C-C appeared to be the entire recognition sequence for *Eco*P1 and, at least in vitro, *Eco*P1 methylated only one strand of the SV40 DNA. The enzyme cleaved the DNA 24-26 nucleotides away in the 3' direction from the site of methylation on one strand and 27-29 nucleotides away on the other strand, giving cuts staggered by 2, 3, or 4 bases, depending on the site. One variant of SV40 has acquired an additional *Eco*P1 methylation and cleavage site by changing an A-G-A-A-C sequence to A-G-A-C-C. (37 refs)

79-2792 Evolutionary Variants of Simian Virus 40: Replication and Encapsulation of Variant DNA. (Eng) Lee, T. N. (NCI, Bethesda, MD 20014); Nathans, D. *Virology* 92(2): 291-298; 1979.

The genomes of evolutionary variants of simian virus 40 (SV40) contain reiterations of DNA sequences derived from the origin of replication of viral DNA. To determine the role of such reiterated DNA segments in the evolution of variants, the relative rates of replication and the encapsidation efficiencies were determined for cloned variants with three, five, six, or nine copies of the SV40 origin sequence. The rate of variant DNA replication relative to that of the helper virus in the variant stock was an exponential function of the number of origin segments per genome. In contrast, encapsidation efficiency was not correlated with the number of origin sequences in the variant genome. It is concluded that a major factor in the evolution of SV40 variants is the replicative advantage conferred by the reiteration of the origin of DNA replication. (14 refs)

79-2793 Purification and Characterization of an Early Glycoprotein from Adenovirus Type 2-infected Cells. (Eng) Persson, H. (Dept. Microbiology, Biomedical Center, S-751 23 Uppsala, Sweden); Signas, C.; Philipson, L. *J Virol* 29(3): 938-948; 1979.

The purification and characterization of an adenovirus type 2 (Ad2) early glycoprotein with an apparent mol wt of 19,000 (E19K) in sodium dodecyl sulfate-polyacrylamide gels are reported. In addition, synthesis of this protein in Ad2-infected HeLa and Ad2-transformed hamster and rat cells was investigated with a monospecific antiserum raised against the purified protein. Purification involved detergent solubilization of membrane fractions from infected cells, followed by affinity chromatography on a lectin column and diethylaminoethyl Sephadex chromatography. The purified material contained three polypeptides (E40K, E19K, E17.5K), with approx 90% of the material being in the E19K moiety. All three polypeptides yielded identical tryptic peptide maps. The E19K polypeptide contained glucosamine as revealed by [³H]glucosamine labeling of infected cells and amino acid analysis of the purified protein. Immunoprecipitation with a monospecific antiserum showed that synthesis of the E19K polypeptide began at 2 hr after infection, with a max rate occurring at 4 hr after infection. The polypeptide was also synthesized at a low rate late in the infectious cycle (12-24 hr postinfection). Immunoprecipitation from three Ad2-transformed hamster embryo cell lines and two Ad2-transformed rat cell lines revealed that one of the hamster cell lines (ad2HE₄) and one of the rat cell lines (A₂T₂C₄) expressed this protein. (33 refs)

79-2794 Premature Termination During Adenovirus Transcription. (Eng) Evans, R. (Rockefeller Univ., New York, NY 10021); Weber, J.; Ziff, E.; Darnell, J. E. *Nature* 278(5702): 367-370; 1979.

Evidence for premature chain termination during the transcription of adenovirus type 2 (Ad2) in HeLa cells is reported. Ad2-specific RNA labeled in vitro in nuclei from infected cells showed a bimodal distribution of Ad2-specific chains, with both large (approx 45S preribosomal RNA) and small (approx ≤18S) sequences being observed. Similar results were obtained in vivo. The 6S-18S region from one preparation was hybridized to a series of fragments of the Ad2 genome prepared by restriction endonuclease digestion. The results indicated that premature RNA chain termination occurred after about 1,000-2,000 nucleotides in vitro and in vivo. To determine the frequency of premature termination, the amount of RNA synthesized in 45 sec that was complementary to a variety of DNA fragments was measured. There was three- to sixfold more labeled RNA complementary to 16.45-18.2 than to any other DNA fragment. In calculating the molarity of transcription from the 11.1-18.2 region, an assumption was made that all transcription reads rightward beginning at

16.45. Thus, three to six times as much transcription occurred in this region as in other regions of the large late transcription unit. Although it was not possible to conclude that there were specific termination sites, the extramolar synthesis did not extend past 25.5-27.9. Very few if any of the extramolar premature transcripts appeared as stable messenger RNA in the cytoplasm. It appears that it is RNA polymerase II that prematurely terminates RNA chains within the first 2,000 nucleotides of the large Ad2 transcription unit. (27 refs)

79-2795 Host Response to Adenovirus 2-transformed Hamster Embryo Cells. (Eng) Cook, J. L. (Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD 20014); Lewis, A. M. *Cancer Res* 39(5): 1455-1461; 1979.

Several adenovirus 2 (Ad2)-transformed LSH hamster embryo cells were isolated, and their tumor-inducing capacity was defined. Ad2 inactivated by UV was used to transform the cells. Evaluation of transformed cell lines produced by Ad2 (prototype strain adenoid 6) or isolates of Ad2 obtained from children in Washington, DC, or West Bengal, India, showed that 13/15 lines induced tumors when injected into newborn inbred LSH or randomly bred NIH hamsters [10^7 cells/hamster, with a median tumor incidence in syngeneic newborns of 65% (range 8%-100%)]. Six of these cell lines did not induce tumors when 10^7 cells were injected sc into weanling animals 21 days old. Similarly derived cell lines transformed by Ad12 or simian virus 40 (SV40) uniformly produced tumors in weanlings following sc inoculation of 10^7 cells. Transplantation of tumors from animals treated as newborns with Ad2-transformed cell lines to other newborns was readily accomplished in 639/640 inoculated newborns. However, only 53/467 weanling hamsters challenged with these tumor lines developed neoplasms. Each of these Ad2-transformed lines contained Ad2 tumor (T) antigen detectable by complement fixation or immunofluorescence. None of six lines yielded Ad2 by Sendai fusion with human embryonic kidney cells or other contaminating agents by a variety of assays. The difference in oncogenicity in weanling hamsters of Ad2-transformed cells and Ad2 newborn tumor lines compared with Ad12- and SV40-transformed cells was not related to tumor dose injected or to differences in in vitro growth properties (eg, doubling times, saturation densities, growth in spinner medium, or colony formation in soft agar). With the two newborn tumor lines tested, weanling rejection of tumor transplants from newborn hamsters could not be overcome by inocula containing 25 times the usual dose of tumor suspension. These two lines produced progressively enlarging neoplasms in 17%-77% of syngeneic weanlings that had been thymectomized as newborns. The results suggest that the production of virus-transformed cells that are not oncogenic in immunocompetent syngeneic hamsters is a general property of Ad2 and that the Ad2-transformed hamster cell system may be a

useful model for studying the interaction of the viral genome, the transformed cell, and developing host immunity in virus-induced carcinogenesis. (32 refs)

79-2796 Thirty-One Human Adenovirus Serotypes (Ad1-Ad31) Form Five Groups (A-E) Based upon DNA Genome Homologies. (Eng) Green, M. (Inst. Molecular Virology, Saint Louis Univ. Sch. Medicine, 3681 Park Ave., St. Louis, MO 63110); Mackey, J. K.; Wold, W. S.; Rigden, P. *Virology* 93(2): 481-492; 1979.

Five distinct DNA homology groups, A to E, were identified among 31 human adenovirus serotypes (Ad1-Ad31) by liquid-phase molecular hybridization with the use of in vitro-labeled viral DNA as a probe. Members within all groups except group A were closely related. In general the DNA homology groupings are consistent with the properties of other "groupings" of human Ad's (oncogenic groups, tumor-antigen groups, G + C content of viral DNA, etc). (60 refs)

79-2797 Transforming Region of Group A, B, and C Adenoviruses: DNA Homology Studies with Twenty-Nine Human Adenovirus Serotypes. (Eng) Mackey, J. K. (Inst. Molecular Virology, Saint Louis Univ. Sch. Medicine, St. Louis, MO 63110); Wold, W. S.; Rigden, P.; Green, M. *J Virol* 29(3): 1056-1064; 1979.

The homology of adenovirus type 5 (Ad5), Ad7, and Ad12 transforming restriction endonuclease DNA fragments with DNA's of 29 Ad types was studied. Ad5 *HindIII*-G (map position 0-7.3), Ad7 *XhoI*-C (map position 0-10.8), and Ad12 (strain Huie) *EcoRI*-C (map position 0-16) and *SaII*-C (map position 0-10.6) fragments were purified, labeled in vitro (nick translation), and annealed with DNA's of Ad1-Ad16, Ad18-Ad24, and Ad26-Ad31. Hybrids were assayed with the use of hydroxylapatite. Ad5 *HindIII*-G hybridized 98%-100% with DNA's of Group C Ad's (Ad1, 2, 5, 6), but only 1%-15% with DNA's of other types. Ad7 *XhoI*-C fragment hybridized 85%-99% with DNA's of Group B Ad's (Ad3, 7, 11, 14, 16, 21), but only 6%-21% with DNA's of other types. Ad12 (Huie) *EcoRI*-C hybridized 53%-68% with DNA's of five other Ad12 strains, 53% with Ad18 DNA, 56% with Ad31 DNA, but only 3%-13% with DNA's of other types. In vitro-labeled Ad12 (Huie) *SaII*-C hybridized 35-71% with DNA's of six other Ad12 strains, 44% with Ad18 DNA, 52% with Ad31 DNA, but only 2%-7% with DNA's of Ad7, Ad2, Ad26, or Ad4. When assayed using S-1 nuclease, *SaII*-C annealed 17%-44% with DNA's of Group A Ad's (Ad12, 18, 31). The melting temperatures of the hybrids of Ad5 *HindIII*-G with all Group C Ad DNA's were 84 C in 0.12 M sodium phosphate (pH 6.8). The melting temperature of the Ad12 (Huie) *EcoRI*-C hybrid with Ad12 (Huie) DNA was 83 C, but it was only 71-77 C with DNA's of other Group A

Ad's. Thus, Groups C and B Ad's both have very homologous transforming regions that are not represented in DNA's of non-Group C Ad's or non-Group B Ad's, respectively. Similarly, Group A Ad's have unique but less homologous transforming regions. These different transforming nucleotide sequences may be reflected in the different oncogenic properties of Groups A, B, and C Ad's in newborn hamsters (highly, weakly, and nononcogenic, respectively). 79-2798 Association of Adenovirus Early Proteins with a Nuclear Fraction That Synthesizes DNA In Vitro. (Eng) Shaw, C. H. (Div. Virology, Natl. Inst. Medical Res., Mill Hill, London NW7 1AA, England); Russell, W. C.; Rekosh, D. M. *Virology* 92(2): 436-448; 1979.

A soluble subnuclear fraction isolated from adenovirus type 5-infected HeLa cells that synthesizes adenovirus DNA in vitro is described. This synthesis is inhibited by immunoglobulins directed against virus-specified proteins synthesized early in infection, but not by immunoglobulins directed against the viral coded tumor antigen (T antigen). Sucrose gradient analysis of the fraction demonstrated that it contained two distinct nucleoprotein complexes. One of these complexes sedimented at about 100S and contained replicating viral DNA molecules. The other, which sedimented at about 40S, contained mature double-stranded DNA of genome length. After a pulse-label with ³⁵S-methionine, the virus-coded 72,000-dalton (72K), single-stranded DNA binding protein (DBP) was found associated with the 100S peak but not with the 40S peak. Following a chase period, however, the DBP also appeared in the 40S peak. Labeling with ³²PO₄ also showed that the phosphorylated form of the 72 K DBP is found initially only in the 100S peak. These results suggest that newly made and phosphorylated DBP associates preferentially with replicating viral DNA. (43 refs)

79-2799 An Adenovirus Protein with the Ends of Replicating DNA Molecules. (Eng) Stillman, B. W. (Dept. Microbiology, John Curtin Sch. Medical Res., Australian Natl. Univ., Canberra, A.C.T. 2601, Australia); Bellett, A. J. D. *Virology* 93(1): 69-79; 1979.

A simple assay for adenovirus DNA-protein complex is described in which DNA, covalently linked to the terminal protein, specifically binds to benzoylethanol-cellulose. The DNA-protein complex can be recovered intact from the column by elution with urea and sodium dodecyl sulfate, or the DNA moiety can be eluted after incubation of the column with protease. With this system, protein was shown to be associated with pulse-labeled single strands of DNA from the terminal restriction enzyme fragments of replicating adenovirus 5 DNA. (42 refs)

79-2800 Three Different Classes of Human Adenovirus Transforming DNA Sequences: Highly Oncogenic Subgroup A-, Weakly Oncogenic Subgroup B-, and Subgroup C-Specific Transforming DNA Sequences. (Eng) Fujinaga, K. (Dept. Molecular Biology, Cancer Res. Inst., Sapporo Medical Coll., Sapporo 060, Japan); Sawada, Y.; Sekikawa, K. *Virology* 93(2): 578-581; 1979.

To compare transforming gene sequences among members of highly oncogenic subgroup A, weakly oncogenic subgroup B, and transforming subgroup C adenoviruses (Ad), DNA-DNA homology measurements were carried out using labeled Ad12 *Hind*III-G (subgroup A), Ad7 *Hind*III-I.J (subgroup B), and Ad5 *Hind*III-G (subgroup C). The measurements revealed three different classes of transforming DNA sequences: one specific for subgroup A (types 12, 18, and 31), the second specific for subgroup B (types 3, 7, and 16), and the third specific for subgroup C (types 2, 5, and 6). The transforming DNA sequences with mol wts of 1.6 to 1.8 x 10⁶ were identical or almost identical members of the same subgroup. One-third or less of the transforming DNA sequences were shared by members of different subgroups. All of the transforming gene sequences were located within a region at the terminal 10% of the viral DNA molecule. The results suggest that different virus-coded transforming proteins are involved in carcinogenesis by these three subgroups of human Ad. (15 refs)

79-2801 Adenovirus-Type-12-induced Rat Brain Tumor Cells: Persistence and Expression of the Viral Genome (Meeting Abstract). (Eng) Ibelgauf, H. (Institut für Genetik der Universität Köln, Cologne, W. Germany); Doerfler, W.; Wechsler, W. *Hoppe Seyler's Z Physiol Chem* 360(3): 289; 1979 (no refs)

79-2802 Identification of Adenovirus Type 12 Candidate Transformation Proteins by Radioimmunoprecipitation with Antisera to *Eco*RI-C-Fragment Transformed Cells. (Eng) Wold, W. S. (Inst. Molecular Virology, St. Louis Univ. Sch. Medicine, 3681 Park Ave., St. Louis, MO 63110); Chinnadurai, G.; Green, M.; Mak, S. *Virology* 94(1): 208-213; 1979.

Polypeptides (PP) coded by early gene block 1 (which includes the transforming region) of Group A human adenoviruses (Ad12, 18, 31) were identified by radioimmunoprecipitation with antisera to *Eco*RI-C fragment-transformed cells. Rat cell lines C-1 and C-2, which were transformed by transfection with the Ad12 *Eco*RI-C fragment (left 16% of genome) were inoculated into syngeneic rats to produce tumors. The tumor sera were used to immunoprecipitate [³⁵S]methionine-labeled PP from Ad12-infected human cells in the early stage of infection. The PP were resolved by electrophoresis in sodium

dodecyl sulfate-polyacrylamide gels and visualized by fluorography. Two additional sera from hamsters bearing tumors induced by inoculation with Ad12 or Ad18 virions were also used. The following PP were immunoprecipitated by the four sera: C-1 serum: 46,000 daltons (46K), 44K, 43K, 40K; C-2 serum: 46K, 44K, 43K, 40K, 16.5K, 10.5K; Ad12 and Ad18 sera: 65K, 60K, 55K, 54K, 47K, 45K, 11K, 10.5K. The sequence relationships between these PP were investigated by the partial proteolysis procedure using *Staphylococcus aureus* V8 protease. The data suggested the following conditions: (1) the C-1- and C-2-specific 46K, 44K, 43K, and 40K PP are highly related; (2) the Ad12- and Ad18-specific 65K, 60K, 55K, 54K, 47K, and 45K PP are highly related; (3) the C-1- and C-2-specific 40-65K PP may be related to, but are not identical with, the Ad12- and Ad18-specific 45-65K PP; (4) all three 10.5K PP are highly related; (5) both 11K PP are highly related and probably are unrelated to the 16.5K or 10.5K PP. The immunoprecipitation results suggest (but do not prove) that the early gene block 1 of Group A Ad's may code a "family" of related PP with apparent mol wts ranging from 40K to 46K or from 40K to 65K, as well as PP of 16.5K and 10.5K. One or more of these PP may play a role in the initiation and/or maintenance of cell transformation. (32 refs)

79-2803 Requirement of Adenovirus Type 12 Gene 401 Function for Initiation of Virus DNA Synthesis. (Eng) Ledinko, N. (Dept. Biology, Univ. Akron, Akron, OH 44325) *J Gen Virol* 42(3): 651-654; 1979.

Virus DNA synthesized in human cells infected with the highly oncogenic adenovirus type 12 (Ad12) temperature-sensitive mutant (H12/*ts*401) following temperature shift-up was characterized. Replicating DNA in human embryo kidney cell cultures infected with either *ts*401 or wild-type human Ad12 was converted into a predominant mature form of virus DNA following a shift from the permissive temperature (31°C) to the nonpermissive temperature (38.5°C). This suggests that the *ts*401 mutant is not defective in virus DNA chain propagation. To determine whether the *ts*401 mutant is defective in the initiation of virus DNA synthesis at the nonpermissive temperature, density labeling experiments in which cells infected with wild-type or *ts*401 virus were incubated with 5-bromodeoxyuridine and ³H-thymidine were carried out. The results showed that the replicating mutant DNA apparently completes a round of replication at the nonpermissive temperature, thereby incorporating bromouracil in the portion of the daughter strand remaining to be replicated. The absence of mutant DNA heavier than hybrid density under the restrictive condition suggests that there is no reinitiation in the replicated molecule. The findings are in agreement with the concept that the gene 401 product is required to initiate, but not to complete, the replication of virus DNA in lytic infection. (8 refs)

79-2804 Cell Origin of Human Adenovirus Type 12-induced Subcutaneous Tumor in Syrian Hamsters. (Eng) Nakajima, T. (Dept. Pathology, Natl. Cancer Center Res. Inst., Tokyo 104, Japan); Mukai, N. *Acta Neuropathol (Berl)* 45(3): 187-194; 1979.

To determine the cell origin of the characteristic adenovirus type 12 (Ad12) tumors derived from the sc tissue of hamsters, Ad12 was inoculated sc into the backs of newborn Syrian hamsters. Twenty-one of 25 animals developed multiple sc tumors close to the inoculation site within 21-90 days; 4 animals also had hepatic neoplasms. Uniform neuroblastic tumor cells forming incomplete rosettes appeared to have encroached into various atrophied muscle fibers. Mitotic figures and bizarre giant cell formations were common. Ad12 virions were demonstrated at each icosahedron symmetry. Many tumor cells possessed a solitary projecting cilium, and cytoplasmic expansions resembling neuroblastic growth cones were also seen. The tumor cells showed numerous tumor (T)-antigen-positive filaments within their cytoplasm. Sequential histologic examination revealed a severe inflammatory reaction, predominantly neutrophilic, at 48 hr. This gradually changed to a lymphocytic reaction that persisted during the 240-hr observation period. Intracytoplasmic T antigens were detectable at 48 hr. The T-antigen-positive cells began to decrease in number and to localize in the muscle layer at 72 hr, and at 240 hr, they retained a close association with the muscle layer. An incipient tumor cell aggregate was found in the interstices of maturing muscle fibers. A sequential study in parallel with electron microscopic examination of normal sc tissue proved that neuroblastic cells closely associated with the muscle spindle anlage could preferentially become the most sensitive target for AD12 tumorigenesis. (21 refs)

79-2805 Cytoplasmic Hepatitis B Surface Antigen and the Ground-Glass Appearance in Hepatocellular Carcinoma. (Eng) Wu, P. C. (Dept. Pathology, Univ. Hong Kong, Queen Mary Hosp. Compound, Hong Kong, China); Lam, K. C. *Am J Clin Pathol* 71(2): 229-234; 1979.

Hepatitis B surface antigen (HBsAg) was identified by an aldehyde fuchsin and immunoperoxidase staining technique and by immunofluorescence in malignant hepatocytes with a ground-glass appearance in only one needle biopsy specimen of a series of specimens taken at a Hong Kong hospital from 130 consecutive patients with hepatocellular carcinoma. The case report of the positive patient, a 14-yr-old girl, is given. HBsAg was identified by aldehyde fuchsin stain in the nonmalignant hepatocytes of 48/83 biopsy specimens that contained nonmalignant liver tissue. The antigen was demonstrable in significantly greater proportions in younger patients. A similar but not identical age relationship was found for hepatitis B antigenemia in Hong Kong. Apparently, the ability to produce HBsAg

declines with age. The usual absence of demonstrable HBsAg in hepatocellular carcinoma cells may be due to a failure of this characteristic to survive into the malignant cell line. Therefore, one cannot rule out the possibility that hepatitis B virus plays a direct role in the pathogenesis of hepatocellular carcinoma. In exceptional circumstances, as when hepatocellular carcinoma appears at an unusually early age, this marker is identifiable in the tumor cells. (24 refs)

79-2806 Crohn's Disease Lymph Node Homogenates Produce Murine Lymphoma in Athymic Mice (Meeting Abstract). (Eng) Das, K. M. (Albert Einstein Coll. Medicine, Bronx, NY 10461); Morecki, R.; Lev, M. *Gastroenterology* 76(5, part 2): 1117; 1979 (no refs)

79-2808 Prostate and Transitional Cell Carcinoma: Radioimmunoassay of Viral Tumor-associated Antigens. (Eng) Mickey, D. D. (Duke Univ. Medical Center, Box 3062, Durham, NC 27710); Paulson, D. F. *Nail Cancer Inst Monogr* (49): 51-63; 1978.

Competition radioimmunoassay was used to detect the p30 core protein of C-type RNA tumor viruses in partially purified extracts from human urothelial tumors. Fourteen

percent of benign hyperplastic and adenocarcinoma tissues were positive for p30 antigen from murine leukemia virus (MuLV) and 22% were positive for feline leukemia virus (FeLV) p30 antigen. Of the extracts from 47 surgical specimens grown in short-term tissue culture, 72% were positive for FeLV antigen, but only 29% of 28 extracts were positive for MuLV antigen. It is unlikely that the cultured cells were producing virus particles and releasing them into the culture medium. Sera collected from patients with urogenital carcinomas at various stages showed no antibody activity. It is concluded that urogenital carcinomas do not contain whole RNA tumor viruses and do not contain viruslike proteins in such quantities that they would be useful as screening reagents. However, competing proteins were present in 25% of the carcinoma tissue tested. Identification of the antigenic cross-reactive proteins as viral or nonviral depends on further purification and characterization. (13 refs)

- 79-2809 **Prevention of Spontaneous Leukemia in AKR Mice by Passive Immunization and Type Specificity of This Protection.** (Eng) Fish, D. C. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD 21704); Gilden, R. V.; Bare, R. M.; Trimmer, R. M.; Huebner, R. J. *J Natl Cancer Inst* 62(4): 943-945; 1979.

The development of spontaneous leukemia in untreated AKR mice and in mice immunized for the first 14 or 31 days of life with goat immune globulin prepared from the sera of goats immunized with radiation leukemia virus was compared. The incidence of leukemia in normal mice at 1 yr of age was 72%, whereas that in mice given 5 immunization injections during the first 14 days of life (Group A) was 19% and that in mice given 10 immunization injections during the first 31 days of life (Group B) was 0%. All differences were significant. By day 500 of life, virtually all untreated mice had died of leukemia, whereas the incidence of leukemia in the Groups A and B mice was 40% and 8% respectively. The incidence at 700 days was still only 8% in the Group B mice. Thus, it appears that the protection in the Group A mice was more in the form of a delay in onset than a complete protection, but essentially lifelong immunization had occurred in the Group B mice. Immune globulin with a high neutralization titer for ecotropic virus provided this lifelong protection, but antibody with a high neutralization titer for murine xenotropic virus did not. (11 refs)

- 79-2810 **The Tumor Dormant State. Comparison of L5178Y Cells Used to Establish Dormancy with Those That Emerge after Its Termination.** (Eng) Weinhold, K. J. (Dept. Microbiology, Thomas Jefferson Univ., Philadelphia, PA 19107); Miller, D. A.; Wheelock, E. F. *J Exp Med* 149(3): 745-757; 1979.

The origin and growth rate of tumor cells that eventually emerge from the tumor dormant state (TDS) were studied by comparing various properties of original and emergent L5178Y lymphoma cells. The TDS established in L5178Y-immunized and -challenged DBA/2 mice was characterized by a prolonged period of clinical normalcy followed by rapid tumor outgrowth. The tumor cells that emerged after termination of the TDS had abnormal marker chromosomes identical to those in the L5178Y cells used in the original challenge inoculum, indicating that the emergent tumor cells were progeny of the challenge inoculum. Original and emergent L5178Y cells had equivalent *in vivo* growth rates when inoculated into normal DBA/2 mice. The emergent L5178Y cells were less susceptible than original cells to *in vitro* lysis by tumor dormant peritoneal cells. Original and emergent L5178Y cells

expressed common tumor-associated target antigens for cytolytic effector cells. Both modulation and masking of these target antigens were ruled out as mechanisms for decreased susceptibility to cell-mediated cytotoxicity. Immunofluorescence revealed heterogeneity in tumor-associated antigen (TAA) expression within both original and emergent cell populations, with decreased intensity of staining in the emergent population. Both populations were equally susceptible to lysis by alloimmune cells, alloantisera, and anti-Thy 1.2 serum, but emergent cells were less susceptible to lysis by serum directed against L5178Y TAA. Quantitative absorption revealed that the emergent L5178Y cells expressed eightfold less serologically detectable TAA than the original cells. These findings indicate that the host immune response developing during establishment of the TDS selects a stable tumor cell subpopulation that expresses decreased amounts of surface tumor-associated target antigens. (25 refs)

- 79-2811 **The Tumor Dormant State. Quantitation of L5178Y Cells and Host Immune Responses During the Establishment and Course of Dormancy in Syngeneic DBA/2 Mice.** (Eng) Weinhold, K. J. (Dept. Microbiology, Thomas Jefferson Univ., Philadelphia, PA 19107); Goldstein, L. T.; Wheelock, E. F. *J Exp Med* 149(3): 732-744; 1979.

Early events involved in establishment of the tumor dormant state are reported and related to the subsequent prolonged clinical remission and eventual termination of tumor dormancy. Sc implantation of DBA/2-derived L5178Y lymphoma cells into DBA/2 mice, followed 10 days later by nodule excision, protected 100% of mice from the rapid outgrowth of an ip challenge of L5178Y cells given 7 days postexcision. Challenged mice remained clinically normal for 48-250 days before the onset of an ultimately fatal tumor outgrowth. The numbers of L5178Y cells in the peritoneal cavity increased logarithmically for 4 days after challenge and then declined to low but detectable levels that persisted throughout the clinically normal period. Cells active in 18-hr *in vitro* cytotoxic assays against ⁵¹Cr-labeled L5178Y target cells were found in the peritoneal cavity. The effector cells were determined to be Thy 1.2-positive. Their activity was tumor-specific and reached peak levels 4 days after tumor challenge and then gradually declined to undetectable levels during the following 70 days. Tumor emergence occurred most frequently during the period when cell-mediated cytotoxicity was no longer demonstrable in the remaining clinically normal mice. A transient peak of low-level cytophilic antitumor antibody was detected about 30 days after tumor cell challenge. The temporal association between the numbers

of tumor cells and the levels of cell-mediated lysis against L5178Y cells indicate the importance of the cell-mediated cytotoxicity response in limiting initial tumor outgrowth and suggest its role as one of the factors responsible for long-term tumor suppression during tumor dormancy. (38 refs)

- 79-2812 Tumor-associated Antigens of Chemically-induced Murine Tumors; The Emergence of MuLV and Fetal Antigens after Serial Passage in Culture.** (Eng) Cleveland, P. H. (Surgical Oncology Service, Dept. Surgery, Univ. California, San Diego, CA); Belnap, L. P.; Knotts, F. B.; Nayak, S. K.; Baird, S. M.; Pilch, Y. H. *Int J Cancer* 23(3): 380-391; 1979.

Using radioiodinated *Staphylococcus aureus* protein A to measure syngeneic, allogeneic, and heterogeneic IgG bound to murine tumor cells, serological analyses of the surface antigens of 3 chemically induced colon carcinomas, 3 chemically induced sarcomas, 1 murine leukemia virus (MuLV)-induced leukemia, 1 radiation-induced leukemia, 1 spontaneous melanoma, and 1 spontaneous sarcoma of BALB/c mice were performed. Unique tumor-associated antigens were found on 3 of the tumors, MuLV-related antigens were found on 8, fetal antigens were found on 7, and two distinct common antigens were found on 7. Common antigen 1 was found on 5/7 latter tumors, and common antigen 2 was found on two. Neither of the common antigens was sarcoma-, carcinoma-, or tissue-type-specific. A number of tumors that did not originally express either MuLV or fetal antigens in primary cultures expressed these antigens after several serial passages in vitro. (40 refs)

- 79-2813 Teratocarcinoma Cells and Cell Surface Differentiation.** (Eng) Edidin, M. (Biology Dept., Johns Hopkins Univ., Baltimore, MD 21218); Ostrand-Rosenberg, S.; Bartlett, P. F. *30th Ann Symp Cancer Res* 67-79; 1978.

The detection of embryo-associated surface antigens on mouse teratocarcinoma cells is reviewed. The properties of the tumor model and the reactivities of some of the antisera prepared against it are covered briefly. Three separate families of antigens were detected by an antiserum prepared against the 402AX teratocarcinoma: antigen I was present on many tumor cells and on teratoma cells but not on normal cells, and it was physically associated with the major histocompatibility (H-2) antigens; antigen II was found in some tumor cells and on teratoma cells; and antigen III was unique to the teratoma cells. Teratocarcinoma cells also expressed antigens determined by some elements of the H-2 complex. Anti-402AX serum reacted well by immunofluorescence with all early stages (up to day 9) of mouse development, antigen I being the predominant teratocarcinoma-defined antigen on the embryos. There was a strong cross-reaction between mouse and human

teratocarcinomas, although the mouse-defined antigens were usually masked on the human tumor. 402AX cells could be destroyed by syngeneic T lymphocytes, and 402AX-sensitized T lymphocytes were able to damage a wide range of tumor cells sharing antigen I. Cells sensitized to the teratocarcinoma in culture were reactive in vitro against cultured embryos. Culture of tumor targets with peritoneal exudate cells resulted in a significant stimulation of cell growth, indicating a potential immune process that acts to promote rather than inhibit growth of the embryo in utero. (39 refs)

- 79-2814 Cell Surface Differentiation of Acute Lymphoblastic cALL-Type Leukemias in Diffusion Chambers.** (Eng) Jager, G. (Institut für Hamatologie der GSF, Landwehrstrasse 61, D-8000 Munich 2, W. Germany); Lau, B.; Pachmann, K.; Rodt, H.; Netzel, B.; Thiel, E.; Huhn, D.; Thierfelder, S.; Dormer, P. *Blut* 38(2): 165-168; 1979.

The peripheral blasts of three untreated patients (2 girls, 1 boy aged 5-11) with childhood acute lymphoblastic leukemia (ALL) were placed in diffusion chambers (5×10^5 cells/chamber) and implanted ip into preirradiated male CBA mice. The chambers were removed on days 6, 9, and 13, and total and differential cell counts were determined. Immunofluorescence studies were performed by labeling the cells with rhodamine-conjugated polyvalent rabbit anti-immunoglobulin (Ig) globulin and anti-T-cell globulin; anti-common ALL globulin (AcALLG) was conjugated with fluorescein. After 6 days of culture, the chamber populations dropped considerably and remained at this level throughout the culture period. Most cells maintained the morphology of leukemic blasts throughout the 13 days. Immunological characterization of the cells revealed marked surface changes. During culture, the percentage of Ig-positive cells simultaneously labeling with AcALLG increased considerably. One explanation of this finding is that most of the ALL blasts in the patients were of the immature B-cell type. Several observations support this view: (1) the morphology of most of the cells remained that of leukemic blasts; (2) growth of normal peripheral mononuclear cells in diffusion chambers does not favor the development of B cells over that of T cells; (3) prior to culturing, many cells of one of the patients carried surface Ig and common ALL antigen simultaneously; 98% of these cells were typically leukemic according to morphological criteria. It seems likely, therefore, that all three ALL's had properties of immature B cells and that the diffusion chamber system allowed these cells to mature. (12 refs)

- 79-2815 Cell-Surface Properties Growth and Malignancy of Haemopoietic Cell Lines (Meeting Abstract).** (Eng) Nilsson, K. (Wallenberg Lab., Univ. Uppsala, Uppsala, Sweden) *Br J Cancer* 39(4): 459-460; 1979 (no refs)

- 79-2816 The Histogenesis of Non-Hodgkin Lymphomas Assessed by Surface Marking (Meeting Abstract).** (Eng) Habeshaw, J. A. (ICRF Medical Oncology Unit, St. Bartholomew's Hosp., London, England); Stansfeld, A. G. *Br J Cancer* 39(4): 483; 1979 (no refs)

- 79-2817 Isolation of a Human B Lymphocyte Membrane Protein with Ia-like Properties.** (Eng) Sullivan, A. K. (Cancer Res. Unit, McGill Univ., Montreal, Quebec, Canada); Jerry, L. M.; Ikeman, R. L.; Mac-cari, R. J.; Li Thi, H.; Sylvester, C. *Can J Biochem* 57(1): 21-31; 1979.

A rapid method for isolating a major surface membrane glycoprotein with immune region-associated (Ia)-like properties from whole, unfractionated cultured human B lymphoblasts is described. The major steps include detergent solubilization, gel filtration, affinity chromatography on Sepharose concanavalin A, and then alkaline acrylamide gel electrophoresis. Specific high-titer rabbit antisera to the isolated protein reacted with cultured and normal peripheral blood B lymphocytes, as well as peritoneal macrophages from a renal dialysis patient. The antisera selectively inhibited the mixed lymphocyte reaction at high dilution. The protein reacted with a heterologous antiserum to HL-B antigens and contained subunits with a mol wt of 33,000 and 27,000, respectively. Resolution of the subunits, however, required a discontinuous sodium dodecyl sulfate gel system. These properties indicate that the protein is similar to murine Ia antigens. The protein was not associated with β_2 -microglobulin, and it showed no structural or antigenic similarity to the major RBC glycoprotein glycophorin. Antisera to the protein failed to precipitate surface-radioiodinated components from similarly treated extracts of cultured human T lymphoblasts. This method now makes available a reference membrane glycoprotein from a differentiated nucleated human cell in sufficient purity and quantity for kinetics and biosynthesis studies. (37 refs)

- 79-2818 Activated Lymphoid Cells Induce Vascularization.** (Eng) Pliskin, M. E. (Dept. Pathology, Univ. Pennsylvania, Philadelphia, PA 19104) *Transplantation* 27(2): 136-138; 1979.

The role of the lymphoid system in the development of neovascularization was investigated. The id injection of phytohemagglutinin (PHA)-treated spleen cells from normal BALB/cByJ mice into syngeneic, whole-body-irradiated recipient mice caused dose-dependent changes in vascularization. Vascularization was enhanced by the PHA-treated spleen cells at doses of 2×10^5 , 5×10^5 , and 1×10^6 ; however, vascularization was inhibited by 4×10^6 cells. Three days following injection of the mitogen-treated cells,

the reaction sites showed increased numbers of polymorphonuclear WBC. The vascular response could have resulted from vasodilation of preexisting blood vessels and/or by angiogenesis. It is postulated, however, that the macrophage in this system may induce angiogenesis as a result of its activation by lymphokines produced by the PHA-treated T cells. (20 refs)

- 79-2819 Spontaneous Human Lymphocyte-mediated Cytotoxicity against Tumor Target Cells. VII. The Effect of Immunodeficiency Disease.** (Eng) Pross, H. F. (Dept. Radiation Oncology, Queen's Univ., Kingston, Ontario K7L 2V7, Canada); Gupta, S.; Good, R. A.; Baines, M. G. *Cell Immunol* 43(1): 160-175; 1979.

Spontaneous lymphocyte-mediated cytotoxicity (SLMC) and antibody-dependent cellular cytotoxicity (ADCC) were assessed in 13 patients with immunodeficiency diseases, 1 with immunodeficiency-thymoma syndrome, 3 with Bruton type agammaglobulinemia, and 9 with common variable hypogammaglobulinemia (CVH). SLMC and ADCC functions were intact (and possibly enhanced) in the thymoma patient. Both ADCC and SLMC were detectable in the patients with X-linked agammaglobulinemia, one of whom had lower than expected SLMC. In all of the immunodeficient patients, the relative inability of B lymphocytes to produce immunoglobulin in vivo or in vitro did not consistently affect the ability of (presumably) other lymphocytes to mediate SLMC and ADCC. However, SLMC in three of the CVH patients was lower than normal. In every case, removal of Fc receptor-bearing cells from the patients' lymphocyte preparations severely depleted SLMC (and ADCC when tested), but cytotoxicity was either unchanged or enhanced by depletion of E rosette forming T cells. The effects of Fc receptor-positive cell depletion, T-cell depletion, culture serum variation, or the addition of antibody-coated erythrocytes to the assay were similar on both SLMC and ADCC effector cells (NK and K cells), regardless of whether patient or normal lymphocytes were tested. The possible significance of the results with respect to surveillance against cancer is discussed. (53 refs)

- 79-2820 The Isolation of Hybrid Cell Lines Producing Monoclonal Antibodies against the p15(E) Protein of Ecotropic Murine Leukemia Viruses.** (Eng) Nowinski, R. C. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA 98104); Lostrom, M. E.; Tam, M. R.; Stone, M. R.; Burnette, W. N. *Virology* 93(1): 111-126; 1979.

Hybrid cell lines were prepared by the fusion of BALB/c mouse myeloma cells with spleen cells of C57BL/6 mice that were immunized with the AKR leukemia K36. Approx 10% of the hybrid cells produced immunoglobulins that reacted in antibody binding assays with AKR murine leukemia

virus (MuLV). Seven independent cell lines were isolated by the combined use of low-density transfer and cloning. These cells produced antiviral antibodies at a level of 3-15 $\mu\text{g}/\text{ml}$ of culture fluid. Syngeneic mice inoculated with the hybrid cells (10^6 ip) developed tumors (hybridomas) that secreted high levels of monoclonal antibodies (5-15 mg/ml) into sera or ascites fluid. Five of the hybrid cell lines produced IgM, one produced IgG₂a, and one produced IgG₂b. In high-resolution two-dimensional polyacrylamide gels, these immunoglobulins showed the limited heterogeneity in heavy and light chains that would be expected for monoclonal products. Radioimmune precipitation assays demonstrated that the monoclonal antiviral antibodies reacted with the p15(E) protein of ecotropic MuLV, but not with the p15(E) protein of xenotropic MuLV. In contrast, rabbit antiserum prepared against purified p15(E) reacted equally well with ecotropic and xenotropic MuLV. The sera or ascites fluids from hybridoma-bearing mice had antibody titers 75- to 100-fold higher than the sera from conventionally immunized mice or rabbits. Serological analysis demonstrated that the monoclonal antibodies reacted with the cell surface of virus-producing leukemia cells, but not with normal thymocytes. Furthermore, monoclonal anti-p15(E) antibodies of the IgG₂a subclass mediated lysis of the ecotropic MuLV virion in the presence of complement. The potential usefulness of monoclonal antibodies in the analysis of viral polymorphism is discussed. (32 refs)

- 79-2821 **The Evolution of Alpha-Chain Disease.** (Eng) Navab, F. (Taj Pahlavi Cancer Inst., P.O. Box 14/1154, Tehran, Iran); Mobarhan, S.; Banisadre, M.; Rambaud, J. C.; Mojtabai, A. *Gastroenterol Clin Biol* 2(12): 983-988; 1978.

Five cases of the digestive form of alpha-chain disease (α -CD) occurring in young (≤ 35 yr) Iranian Moslems, two of whom (the 2 female patients) belonged to a high socioeconomic group, are reported. Three patients presented with the usual clinical features of α -CD, chronic diarrhea being the main symptom. The fourth patient was seen at a late phase of the disease, and he had clinical and radiologic evidence of an overtly malignant intestinal tumor. He died within 4 days. The fifth patient presented with obstruction of the small intestine of 1 mo duration as the only clinical feature. A short, narrow, and ulcerated jejunal area with plasmacytic infiltration into the serosa was demonstrated microscopically; this type of lesion is unusual during the early phase of the disease. Stage A lesions were identified in two patients, both of whom responded to chemotherapy. The disease progressed to an immunoblastic sarcoma in the other two patients after a 30- and 21-mo clinical remission, respectively. One of these patients was asymptomatic, and the alpha-chain protein was no longer detectable in the serum when sarcoma was diagnosed. A complete remission was achieved by total abdominal irradiation and combination chemotherapy. (15 refs)

- 79-2822 **Increased Frequency of Gm(2) in Whites with Malignant Melanoma (Meeting Abstract).**

(Eng) Pandey, J. P. (Dept. Basic and Clinical Immunology, Medical Univ. South Carolina, Charleston, SC); Fudenberg, H. H.; Hersh, E.; Gutterman, J. *Clin Res* 27(2): 4734; 1979. (no refs)

- 79-2823 **Skin Cancer Development in Mice Exposed Chronically to Immunosuppressive Agents.**

(Eng) Daynes, R. A. (Dept. Pathology, Univ. Utah Sch. Medicine, Salt Lake City, UT, 84132); Harris, C. C.; Connor, R. J.; Eichwald, E. J. *J Natl Cancer Inst* 62(4): 1075-1081; 1979.

Experiments designed to establish the presence or absence of a relationship between the incidence of neoplasia and the chronic administration of immunosuppressive (IS) drugs are reported. Murine mammary tumor virus-negative inbred female C3Hf/HeN mice were exposed to UV light (dose rate 1.79×10^3 ergs/cm²/sec over the wavelength range 280-320 nanometers; 3 10-min exposures/wk) or benzo(a)pyrene (BP: 50 μ ; of a 0.05% soln applied topically 2x/wk) until tumor development or death. Mice in each carcinogen treatment group were also subjected to four different chronic IS regimens to determine their effect on skin cancer development. The IS agents were cyclophosphamide (30 mg/kg/wk ip), methotrexate (2.0 mg/kg 3x/wk ip), cortisone acetate (2.5 mg/wk), and heterologous antilymphocyte globulin (1.6 mg 3x/wk). IS treatment was continued until drug-related (subjective evaluation) mortality reached 10%. Because of an unexpectedly high morbidity and mortality of mice exposed to chronic IS measures, dosages were kept at a level that permitted them to survive but did not prolong allogeneic skin graft survival and lower antibody titers or diminish the proliferative responses of lymphocytes to mitogens or allogeneic lymphocytes. Nevertheless, the latency periods (time interval between beginning of medication and appearance of skin tumors) of tumors in mice exposed to IS measures were significantly shortened in several groups of mice exposed to UV + cyclophosphamide, cortisone, or antilymphocyte globulin and mice exposed to BP + cortisone. In three groups, spindle cell tumors (fibrosarcomas) shifted to squamous cell carcinomas. A suppressed immune function would not be regarded as the mechanism for the observed responses, because immunosuppression was not detected in the experimental mice. (18 refs)

- 79-2824 **Release of Soluble "Blocking" and "Suppressor" Factors from Normal Lymphocytes Treated**

with RNA from Spleens of Tumour-bearing Mice. (Eng) Pennline, K. J. (Dept. Microbiology, Schs. Medicine and Dentistry, Georgetown Univ., Washington, DC, 20007); Evans, S. B.; Nawrocki, J. F.; Rees, J. C.; Johnson, C. S.; Vallera, D. A.; Dodd, M. C. *Br J Cancer* 39(3): 247-258; 1979.

Investigations were made of the possibility of transferring "negative" or "suppressive" types of immune activity with RNA. RNA extracted from the spleens of tumor-bearing (TLRNA) and tumor-immune (ILRNA) C3H/HeJ mice was shown to transfer to normal lymphocytes (NL) the ability to produce factors that block specific tumor cell cytotoxicity and mediate specific antibody-dependent cell cytotoxicity (ADCC). Aliquots of normal C3H mouse lymphocytes were treated with TLRNA or ILRNA and cultured in vitro in the absence of tumor antigen. Supernatants were collected at 24-hr intervals and tested in a microcytotoxicity assay for blocking and ADCC activities. Factors that inhibited tumor destruction by specifically sensitized lymphocytes at the level of both the tumor cells and effector cells were demonstrable in culture supernatants of NL pretreated with TLRNA (50 or 100 $\mu\text{g}/4 \times 10^6$ cells) but not ILRNA. However, treatment of NL with either RNA resulted in the production of factors that mediated tumor-specific ADCC. Cytotoxicity testing and absorption studies of the tumor cell and a control cell indicated that factors mediating ADCC and blocking at the target cell level were specific for the tumor. Suppressor activity at the effector cell level was not absorbed by tumor cells and represents a separate and distinct mechanism of immunosuppression. These data indicate that RNA faithfully transfers "suppressive" as well as "positive" types of immune responses that have been reported previously for lymphocytes obtained directly from tumor-bearing and tumor-immune animals. (37 refs)

79-2825 Immunobiology and Therapeutic Manipulation of Heterotransplanted Nb Rat Prostate Adenocarcinoma into Congenitally Athymic (Nude) Mice. I. Hormone Dependency and Histopathology. (Eng) Drago, J. R. (Dept. Urology, Sch. Medicine, Univ. California at Davis, UCD Medical Center, 4301 X St., Suite 249, Sacramento, CA, 95817); Gershwin, M. E.; Maurer, R. E.; Ikeda, R. M.; Eckels, D. D. *J Natl Cancer Inst* 62(4): 1057-1066; 1979.

Nb rat prostate adenocarcinomas, induced by the administration of testosterone and estrogen implants, were serially studied as heterotransplants in congenitally athymic (nude) mice. This tumor model is similar to human prostate adenocarcinoma. Eight Nb rat tumors (androgen-dependent tumors 2 Pr-125, 2 Pr-128, and 2 Pr-129-D-11A; estrogen-dependent tumors 52 Pr-16 and 52 Pr-14B; and autonomous tumors 13 Pr-12, 102 Pr-22, and Pr-90) were serially transplanted. The latency period, histology, and hormone characteristics of the various tumors remained stable through 12 transplant generations. The hormone dependency pattern also remained stable. Despite the deficiency of cell-mediated immunity in the nude mouse, the rate-limiting step for successful transplantation appeared to be the hormone status of the host. Such a tumor-hormone interaction may be critical in the ability or failure to transplant specific human tumors into the nude mouse. In additional experiments, the chemotherapeutic responsiveness of heterotransplanted adenocarcinoma 13 Pr-12 was evaluated. This prostate tumor was uninfluenced by hor-

mone manipulation. The effectiveness of 5-fluorouracil, cyclophosphamide, adriamycin, and methotrexate was statistically significant, ($p < 0.003$). This combination of animal model systems proved useful in the evaluation of chemotherapeutic agents heretofore having limited use by urologic oncologists. (42 refs)

79-2826 Accessory Cell Requirements for Lymphoma Growth In Vitro and in Irradiated Mice. (Eng) Umetsu, D. T. (Dept. Pathology, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016); Lerman, S. P.; Thorbecke, G. J. *Cell Immunol* 42(1): 139-154; 1979.

Accessory cell requirements for growth of the transplantable B-cell lymphoma PU-5 and a transplantable reticulum cell sarcoma (RCS) were determined in vivo and in vitro studies. The growth of PU-5 was markedly diminished in γ -irradiated compared with normal BALB/c mice. Transfer of bone marrow, but not of lymph node or peritoneal exudate cells, partially restored the ability of irradiated mice to support lymphoma growth. In vitro growth of PU-5 cells was promoted by silica-sensitive, adherent cells bearing surface immune region-associated (Ia) antigen that were present in peritoneal exudates, spleen, and lymph nodes, but not in bone marrow. Their similar action on PU-5 growth occurred only in rocking cultures. The cells did not have to be histocompatible, and they acted synergistically with 2-mercaptoethanol (2-ME) in the medium. This synergism suggested that two different stimulating effects were involved. The growth-promoting action in vitro was decreased 24 hr after γ -irradiation of the adherent cells in vitro. Growth of a transplantable RCS in SJL/J mice had previously been shown to be inhibited by prior irradiation of the host and to be restored by transfer of lymphoid cells containing a phagocytic component, but in the present studies no consistent growth-promoting effect of accessory cells on RCS's was demonstrated in vitro. Both lymphomas were stimulated by the presence of 2-ME in stationary cultures. The relationship between the in vivo and in vitro lymphoma growth-promoting activities of macrophagelike cells is analyzed. (84 refs)

79-2827 Discrepant Effects of Interferon on Murine Syngeneic Ascites Tumors and Their Solid Metastasizing Counterparts. (Eng) Ryd, W. (Inst. Pathology, Univ. Gothenburg, Gothenburg, Sweden); Hagmar, B.; Lundgren, E.; Strannegard, O. *Int J Cancer* 23(3): 397-401; 1979.

The effects of interferon (IF) on CBA and C57BL/6J mice with transplanted nonviral ascites tumors were studied. IF (12,500 units/day ip for 10 days starting the day after tumor transplant) prolonged survival time in mice inoculated ip with one of two ascites tumors and caused one of the tumors to grow in predominantly solid rather than disseminated form. There was no effect on survival time following inocula-

tion of a more virulent ascites tumor. In a second study, ascites tumors were inoculated sc, and IF was given for 11-15 days beginning with the onset of metastasis. When ascites tumors are transplanted sc, they grow as solid tumors. The mean tumor wts were higher in all IF-treated mice compared with untreated controls, and mean survival times were reduced. In mice receiving one of the less virulent tumors, the tumor-enhancing effect was highly significant and there was a highly significant increase in the development of lung metastases. The incidence and distribution of metastases were not affected by IF in the mice receiving the other two tumors. Animal models for analyzing IF effects should be developed before IF treatment is initiated in human cancer patients. (32 refs)

PATHOGENESIS

79-2829 Genetic Mechanisms in Cancer Predisposition. Report of a Cancer Family. (Eng) Meisner, L. F. (State Lab. Hygiene, 465 Henry Mall, Madison, WI, 53706); Gilbert, E.; Ris, H. W.; Haverty, G. *Cancer* 43(2): 679-689; 1979.

A lower middle class black family is described in which four siblings developed cancer affecting different organs: lymphoma, meningeal sarcoma, osteogenic sarcoma, and adenocarcinoma of the cecum (proband). Antibody titers to Epstein-Barr virus were elevated in all family members except the proband. All family members had normal chromosome constitutions, but a specific fragile site leading to breakage of the long arm of chromosome 16 was found in the father, proband, and two normal sibs. Chromosome preparations from skin biopsies of five unaffected family members demonstrated excessive polyploidy due to endoreduplication that was probably caused by mycoplasma. There was only one other case of cancer in previous generations of this family. There may be at least three nonlinked genetic loci associated with cancer susceptibility that in certain combinations can give rise to the cancer family syndrome. By themselves, these loci would not be significant relative to cancer predisposition. The first locus could be a common gene akin to an oncogene or a provirus. The second could be a germinal or somatic regulatory gene, and the third could be a gene affecting immunocompetence. The dominant oncogene would make for cancer susceptibility, whereas the controlling genes of the other two loci could be associated with cancer resistance, since two mutations would then be required for malignant development. This model would also explain the distribution of cancer susceptibility and resistance in the general population. (57 refs)

79-2830 Chromosome Aberrations of Myeloid and Lymphoid Cells in Cancer Patients and Family Members without Evidence of Cancer. (Eng) Wurster-Hill, D. H. (Dept. Pathology, Dartmouth Medical Sch., Hanover, NH); Cornwell, G. G.; McIntyre, O. R. *Cancer Detect Prev* 2(1): 125-146; 1979.

Studies of chromosome (CS) aberrations of myeloid and lymphoid cells in cancer patients and family members without evidence of cancer are reviewed. CS banding techniques permit the identification of each CS individually and thus facilitate accurate analyses of CS abnormalities. Banding studies to date have clearly demonstrated a nonrandom involvement of certain CS's in the formation of abnormal cell lines in individuals with hematological disorders. Thirteen different

CS's participate in this phenomenon, which is known as clustering. They are CS's 1, 7-9, 14, 17-22, X, and Y, and the disorders with which they are associated include myeloproliferative disorders, myelomas, lymphomas, acute myelogenous leukemia, chronic myelogenous leukemia, anemias, ataxia-telangiectasia, plasma cell leukemia, and non-Hodgkin's lymphoma. Clinically normal relatives of cancer patients with cancer and cancer-prone conditions may also have abnormal clones or CS instability. Two families in which there was increasing CS instability and mitotic activity in the unstimulated blood cultures of four clinically normal members are described. These phenomena indicate the presence of a dynamic process that might be envisioned as one or more chromosomally normal inheritable defects in DNA repair or CS replication that are especially responsive to the detrimental effects of environmental mutagens. Mutagenic stimulus would then promote the occurrence of random or semirandom errors, some of which would be reflected in CS abnormalities. The latter might produce a clone with a constitution compatible with the development of neoplasia. Clustering may reflect the receptor sites for mutagenic agents and/or the genetic loci for the growth control and differentiation of specific cell types that become malignant, or it may result from an altered milieu permissive of clone development and survival and associated with particular etiologic agents. 79-2831 Hodgkin's Disease in Siblings. (Ger) Theiss, W. (Hamatologie und Onkologie, Klinikum rechts der Isar der Techn. Universität, Ismaninger Strasse 22, D-8000 Munich 80, W. Germany); Sauer, E.; Rastetter, J. *Munch Med Wochenschr* 121(9): 309-312; 1979.

The occurrence of histologically diagnosed Hodgkin's disease (HD) in a pair of brothers and a pair of sisters is reported, and similar cases in the literature are reviewed. The first patient was found to have lymphocyte-rich HD in 1946, at age 8; his brother was diagnosed with nodular-sclerotic HD Stage IV in 1973, at age 21. Two other brothers, the parents, and other close relatives had no history of tumors or systemic diseases. Nonclassifiable HD Stage II was found in a 22-yr-old girl in 1970. Her sister developed nodular-sclerotic HD in 1977, at age 33; from 1972-1975, she had tuberculosis of the submandibular nodes. No tumors or systemic disease were found in a brother and sister of this pair, their parents, and other relatives. A literature search showed an incidence of 13 sibling pairs among 3,332 cases of HD; this frequency of siblings is higher than that expected from a random incidence ($p < 0.001$). The findings of sex concordance in 12/13

pairs is also significant ($p < 0.01$). Further pairs found in isolated case reports bring the total to 32 pairs of brothers, 12 pairs of sisters, and 17 sex-discordant pairs. Thus, the increased risk of HD for same-sex siblings is calculated to be 2.5 times that for discordant siblings. There is an approx sevenfold increased risk of the disease for siblings of HD patients (assuming diagnosis is made before either is 45 yr old). It appears that HD has a tendency to be familial; the contribution of genetic and environmental factors cannot yet be evaluated. (51 refs)

79-2832 Genetic Mosaicism and In Vivo Analyses of Neoplasia and Differentiation. (Eng) Mintz, B. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA, 19111). *30th Ann Symp Cancer Res* 27-53; 1978.

Two experimental approaches were employed to study the developmental nature of neoplastic disease: (1) strain-specific malignancies in mice were used to obtain allophenic individuals in which tumor-susceptible and nonsusceptible cell strains coexist throughout life and (2) frankly malignant stem cells were brought into contact with normal, early stem cells in young embryos. Genotypic analyses in allophenic animals revealed that tumor susceptibility was largely localized to the cells of the potentially malignant tissue. As a result of transplant experiments with genetically mosaic nodules, a hypothesis of early mammary tumorigenesis in ordinary (single genotype) animals was advanced. It was hypothesized that normal cells may usually be closely associated with transformed cells at first and may be indispensable for the ultimate capacity of the latter to grow and proliferate independently. A similar supportive role of associated normal cells may characterize the early stages of other malignancies. Multiclonality in hepatomas, and possibly in some other kinds of tumors, may be more common than analyses of tumors from allophenic mice have shown. Experiments in which teratocarcinoma cells were normalized after they were injected into blastocysts are described. The experimental use of genotypic cellular mosaicism in early embryos furnished the first unequivocal case of complete and stable reversal of an animal malignancy to normalcy. The initial conversion to malignancy in teratocarcinomas may come about through induced changes in gene function, rather than gene structure, because of an anomalous environment. Both mutational and nonmutational classes of cancers probably exist: many tumors may be caused by somatic mutation, whereas nonmutational cancers may result from physiological changes in the cell or tissue milieu. Cells may lose their transformed phenotypes if an oncogenic virus is lost or if the cellular chromosome constitution changes in specific ways. Regarding the possible developmental totipotentiality of malignant teratocarcinoma cells, the first instance of mammalian organismic differentiation from preselected mutant cells by a "parasexual" route was demonstrated. (76 refs)

79-2833 Acute Lymphoblastic Leukemia Accompanied by an Eosinophilia of the Peripheral Blood and

the Meninges (Letter to Editor). (Fre) Youinou, P. (Hopital St-Louis, 2, place du Dr. A. Fournier, F 75475 Paris Cedex 10, France); Andrieu, J. M.; Casassus, P. *Nouv Presse Med* 8(7): 527; 1979.

The case is presented of an 8-yr-old child who had a high blood eosinophil count ($10,400/\text{mm}^3$) when leukemia was initially diagnosed. After 16 mo of chemotherapy, eosinophils appeared in the spinal fluid ($140/\text{mm}^3$). The patient died 41 mo after diagnosis with high eosinophil counts in both blood and spinal fluid. (5 refs)

79-2834 A Case of Preleukemia--Reconstitution of Normal Marrow Function after Bone Marrow Transplantation (BMT) from Identical Twin. (Eng) Bhaduri, S. (Dept. Internal Medicine and Pediatrics, Div. Haematology, Univ. Ulm, Steinhovelstrasse 9, D-7900 Ulm/Donau, W. Germany); Kubanek, B.; Heit, W.; Pflieger, H.; Kurrle, E.; Fliedner, T. M.; Heimpel, H. *Blut* 38(2): 145-149; 1979.

The reconstitution of normal bone marrow (BM) function in a 30-yr-old man with preleukemia who received a bone marrow transplantation (BMT) from his identical twin brother is reported. A tentative diagnosis of preleukemia had been made 4 yr previously on the basis of a severe sideroblastic anemia, micromegakaryocytes in the BM, and granulocytopenia. Biopsy 4 yr later showed a hypercellular BM consisting mostly of normoblasts and proerythroblasts, hyperplasia of megakaryocytes, and a complete absence of myelopoiesis. Repeated cytogenetic analysis of the BM revealed that 75% of all metaphases had an extra C-group chromosome. The decision for a BMT was made because of progression of the disease and the danger presented by repeated life threatening infections. The patient received 2.14×10^8 cells/kg body wt. BM biopsies taken at weekly intervals after the BMT showed a steadily increasing cellularity of the BM with a nearly normal picture after 6 wk. Cytogenetic analysis of the BM 3 wk after transplantation revealed a normal karyotype. BM cell count and colony-forming units showed near normal values after 6 wk. (5 refs)

79-2835 Acute Leukemia Complicating Hodgkin's Disease. Five New Cases. (Fre) Jouet, J. P. (Service des Maladies du Sang, Hopital A. Calmette, C.H.U. de Lille, F 59000 Lille, France); Huart, J. J.; Bauters, F.; Goudemand, M. *Nouv Presse Med* 8(8): 613-614; 1979.

Acute nonlymphocytic leukemia was diagnosed in 3 men and 2 women 32-61 mo (av 4 yr) after the diagnosis of Hodgkin's disease. All patients had received polychemotherapy with nitrogen mustard, vincristine, procarbazine, and prednisone for Hodgkin's disease. Two patients were also irradiated. (4 refs)

79-2836 Malignant Lymphomas: Models of Differentiation and Cooperation of Lymphoreticular Cells.

(Eng) Lennert, K. (Dept. General Pathology and Pathologic Anatomy, Univ. Kiel, D-2300 Kiel, W. Germany); Kaiserling, E.; Muller-Hermelink, H. K. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 897-913; 1978.

Methods of identifying various types of structural cells in normal lymphatic tissue are described, and evidence indicating that specific reticulum cells (RC) are associated with the formation of T and B areas during ontogeny is presented. Four types of RC can be identified in normal human lymphatic tissue by ultrastructural and cytochemical criteria: dendritic (B-cell regions only), interdigitating (T-cell regions only), histiocytic (T- and B-cell regions), and fibroblastic (predominantly at borders of T-cell regions). The various types of RC can also be easily differentiated by enzyme cytochemistry, as characteristic patterns are found for several surface and intracytoplasmic enzymes. The different types of RC are recognizable by light microscopy only with great difficulty, if at all. A characteristic pattern of dendritic or interdigitating RC is found in some low-grade malignant non-Hodgkin's lymphomas of B- or T-cell origin, respectively. Centroblastic/centrocytic lymphoma consists of all cells found in reactive germinal centers, including dendritic RC. Centrocytic lymphoma, another germinal-center neoplasm, also contains dendritic RC, but other B-cell lymphomas are devoid of dendritic RC. T-zone lymphoma contains all elements of T-cell areas, including interdigitating RC. Interdigitating RC are also found in mycosis fungoides, Sezary's syndrome, and T-cell-type chronic lymphocytic leukemia. High-grade malignant lymphomas of B- or T-cell origin usually do not reveal specific RC. Thus, a characteristic pattern of RC reflects the degree of differentiation of a non-Hodgkin's lymphoma. The findings in Hodgkin's disease suggest that it may also be subclassified into at least two biologically different types. The nodular variant with lymphocytic predominance (nodular paraneoplasia) is the neoplastic counterpart of progressively transformed germinal centers, whereas the nodular sclerosing and mixed types of Hodgkin's lymphoma develop in and involve mainly T regions. This difference is reflected by different patterns of specific RC. The findings in malignant lymphomas support the microecologic view of lymphatic tissue. (36 refs)

79-2837 No Maternal Effect in Childhood Leukaemia with Neurofibromatosis (Letter to Editor). (Eng) Bader, J. L. (Clinical Epidemiology Branch, NCI, Bethesda, MD, 20014); Miller, R. W. *Lancet* 1(8114): 503; 1979.

Lineal transmission of neurofibromatosis (NF) in 22 children with the nonlymphoblastic form of leukemia (NLL) was examined. Although maternal transmission occurred in 13 patients (vs paternal in 5 and spontaneous mutation in 4), the excess was not significantly greater than the expected maternal:paternal transmission ratio of 1.82:1. Thus, although maternal (intrauterine) factors apparently exacerbate non-hematological manifestations of NF, different factors probably enhance the induction of NLL. (7 refs)

79-2838 Chromosome Studies of Two Transplantable Leukemias of BN Mice. (Eng) Bregula, U. (Dept. Tumor Biology, Inst. Oncology, 00-973 Warsaw, Poland); Wlodarska, I.; Wezyk, J. *J Natl Cancer Inst* 62(4): 1051-1056; 1979.

Karyotypes of two transplantable murine ascites leukemias, LBN/a2 and LBN/b3, were studied with the use of the trypsin-Giemsa technique. The original tumors arose in adult female mice of strains BN/a and BN/b after prolonged antilymphocyte globulin administration. The karyotypes of both leukemias showed similar patterns. Both were hyperdiploid with modal chromosome numbers of 41 and 42 in LBN/a2 and LBN/b3, respectively. The cells consisted of an average of 37 normal chromosomes and 4-5 abnormal chromosomes. The most consistent karyotype deviation was monosomy of the X-chromosome and of several autosomes: #9, 14, and 7 in the LBN/a2 line and #7, 12, 14, and 9 in the LBN/b3 line. In most LBN/b3 cells and in a lower proportion of LBN/a2 cells, trisomy of chromosome #15 was found. With regard to the occurrence of abnormal marker chromosomes, both tumors exhibited great cell-to-cell variation. Two of the markers were common to both leukemia lines. (23 refs)

79-2839 Human Myeloproliferative Disorders: Clonal Origin in Pluripotent Stem Cells. (Eng) Fialkow, P. J. (Medical Genetics Section, Medical Service, Veterans Admin. Hosp., Seattle, WA, 98108); Denman, A. M.; Singer, J.; Jacobson, R. J.; Lowenthal, M. N. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; pp. 131-144; 1978.

Application of the glucose-6-phosphate dehydrogenase marker system to three myeloproliferative disorders, chronic myelocytic leukemia (CML), polycythemia vera, and idiopathic myeloid metaplasia, showed that each disease involved pluripotent stem cells. Furthermore, the disorders had a clonal origin at the time of diagnosis. The data do not support hypotheses of an origin from the proliferation of normal stem cells; they are much more compatible with a neoplastic origin. The clinical manifestations of each disease are quite different. It is not known whether these manifestations differ because there are different kinds of genetic alterations governing the response of proliferating cells to regulatory factors and/or because different levels of stem cells are involved in each disease. Few normal uncommitted stem cells have been found in CML, but the presence of these cells has been documented in polycythemia vera. Lymphocytes with B-cell characteristics arise from the abnormal CML stem cell. There are two other populations of lymphocytes in patients with CML, and both have T-cell characteristics. One population of T cells may arise from the abnormal CML stem cell, but the other population definitely does not. Marrow fibrosis is the predominant feature in idiopathic myeloid metaplasia and is a not-infrequent occurrence in CML and polycythemia vera. Data suggest that marrow fibrosis is a secondary event

and not an integral part of the abnormal clonal proliferation. (41 refs)

- 79-2840 Adult Lymphoid Neoplasias of T- and Null-Cell Types.** (Eng) Koziner, B. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Mertelsmann, R.; Filipa, D. H.; Good, R. A.; Clarkson, B. D. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; pp. 843-857; 1978.

The clinical, morphological, cytochemical, and cell-marker features of T- and null-cell adult lymphoid neoplasias are presented. Twenty-six patients with acute lymphoblastic leukemia (ALL) and 18 patients with leukemic malignant lymphoma of the diffuse, poorly differentiated, lymphocytic (DPDL) lymphoblastic variety were characterized. There were several similarities between ALL and the DPDL lymphoblastic type in the leukemic phase, which suggested common cell lineages with variable expression in different tissues. Clinically, the DPDL patients had a higher incidence of initial mediastinal and CNS involvement than did the ALL patients. Both entities comprised cases with a predominance of either null or sheep RBC-rosetting cells at 4 and 37 C. There were 8 and 10 patients, respectively, in the T and null-cell DPDL groups, 4 patients had T-cell ALL, and 22 patients had null-cell ALL. High levels of terminal deoxynucleotidyl transferase (TdT) activity were detected in the bone marrow and peripheral blood of all 30 patients studied. A statistically significant relationship was found between the presence of nuclear convolutions and the T-cell type of leukemic disorder. Mediastinal involvement was observed in 9/17 cases with and 9/27 cases without convoluted nuclei. No difference in TdT activity was detected between the two groups. A positive reaction for acid phosphatase in the paranuclear zone was observed in association with nuclear convolutions and rosetting capacity. Analysis of patients studied within the last 2 yr and receiving intensive chemotherapy showed no significant differences in survival between the DPDL and ALL patients, between cases with a predominance of T vs null cells, or between cases with a convoluted vs nonconvoluted nuclear morphology. These studies suggest that the presence of high levels of TdT activity, sheep RBC-rosetting capacity, a convoluted nucleus, and strong acid phosphatase content in the paranuclear area probably denote properties of neoplastic cells of thymic lineage. The variable expression of these markers might represent proliferation at different levels of differentiation and/or phases of the cell cycle. (25 refs)

- 79-2841 The Ultrastructure of Liposarcoma. A Study of 10 Cases.** (Eng) Kindblom, L. G. (Dept. Pathology, Sahlgren's Hosp., Univ. Goteborg, Goteborg, Sweden); Save-Soderbergh, J. *Acta Pathol Microbiol Scand [A]* 87(2): 109-121; 1979.

An ultrastructural study of 10 human liposarcomas is report-

ed. Four of the liposarcomas were well-differentiated, lipomalike, and/or fibrosing; three were myxoid tumors; two were round cell tumors, and one was a pleomorphic tumor. The well-differentiated, lipomalike liposarcomas contained cells with a few large lipid droplets, few organelles and a peripherally located, fairly large nucleus. The well-differentiated, fibrosing liposarcomas contained mostly spindle-shaped, fibroblastlike cells, with abundant rough endoplasmic reticulum and inconspicuous lipid inclusions, surrounded by collagen. One well-differentiated liposarcoma had an area that was similar to brown adipose tissue and hibernoma. The spindle and stellate cells of the myxoid liposarcomas showed abundant rough endoplasmic reticulum and large smooth-membraned vacuoles filled with moderately dense amorphous material, which appeared to be extruded extracellularly by rupture of the vacuoles. Cytoplasmic lipid droplets were seen in most cells, but they were much less prominent than in the well-differentiated lipomalike liposarcomas. Ultrastructurally, there were many similarities between the myxoid and round cell liposarcomas, indicating a close relationship between the two types. The pleomorphic liposarcoma revealed cells with one or more large, irregular nuclei, numerous large vacuoles from dissolved lipids, abundant dilated cisternae of rough endoplasmic reticulum, and round, electron-dense bodies corresponding to PAS-positive hyalin globules seen in the light microscope. It is suggested that the variegated cellular appearance of the different liposarcoma subtypes reflects the wide cellular spectrum seen during the differentiation of adipose tissue and that, histogenetically, all liposarcomas represent a single entity. (15 refs)

- 79-2842 Myxoid Variant of Malignant Fibrous Histiocytoma. Ultrastructural Observations.** (Eng) Lagace, R. (Departement de Pathologie, Universite Laval, Cite Universitaire, Quebec, Canada G1K 7P4); Delage, C.; Seemayer, T. A. *Cancer* 43(2): 526-534; 1979.

Ultrastructural findings in four cases of the myxoid variant of malignant fibrous histiocytoma (MFH) are presented. Light microscopy demonstrated a pseudocapsule composed of moderately vascularized dense connective tissue at the margin of all neoplasms. Two different growth patterns were apparent: in one, a myxoid, poor cellular stroma was dominant; in the other, the tumor was more cellular and demonstrated a storiform pattern. Abundant stromal mucopolysaccharides were present in the myxoid stroma. Electron microscopy (EM) demonstrated four principal cell types in the myxomatous portions of the neoplasms: a primitive mesenchymal cell, spindle cells of a fibroblastic and histiocytic nature, and multinucleated giant cells. It is unlikely that EM could be consistently decisive in differentiating myxoid MFH from other myxomatous lesions of mesenchymal soft tissue, since they share considerable structural similarities. The observations in this study support the concept that fibroblasts and histiocytes arise from the same mesenchymal stem cell. (22 refs)

- 79-2843 Case Report: Association of Giant Cell Arteritis and Pituitary Tumor. Report of Two Cases.** (Eng) Papaioannou, C. C. (Dept. Internal Medicine, Div. Rheumatology, Mayo Clinic, Rochester, MN, 55901); Trautmann, J. C.; Kazmier, F. J.; Hunder, G. G. *Am J Med Sci* 277(1): 85-90; 1979.

The cases of two patients with giant cell arteritis and a concomitant pituitary tumor are reported. The first patient, a 63-yr-old man, presented with a history of headache, fever, and visual blurring. The second patient, a 69-yr-old woman, presented with scalp tenderness, ear pain, headaches, and visual blurring. They were diagnosed as having giant cell arteritis. However, skull roentgenograms revealed an enlarged sella turcica in both patients, a finding that was confirmed by tomograms of the sella. Arteriograms showed the presence of vascular pituitary tumors that were removed transphenoidally. The tumors were chromophobe adenomas, the most common pituitary tumor. Symptoms include orbital headaches, visual disturbance and visual field loss, and hypo- or hyperpituitarism. These two cases illustrate the importance of a careful neuroophthalmologic examination and roentgenograms of the head in patients with giant cell arteritis who have visual field loss. (25 refs)

- 79-2844 Familial Thyroid Adenomata (Meeting Abstract).** (Eng) Schiffrin, A. (McGill Univ., Montreal, Canada); Guyda, H.; Hughes, I.; Winter, J. *Pediatr Res* 13(4, part 2): 385; 1979. (no refs)

- 79-2845 C-Cell Hyperplasia and Medullary Thyroid Carcinoma in the Rat. An Immunohistochemical and Ultrastructural Analysis.** (Eng) DeLellis, R. A. (Dept. Pathology, Tufts Univ. Sch. Medicine, Boston, MA, 02111); Nunnemacher, G.; Bitman, W. R.; Gagel, R. F.; Tashjian, A. H.; Blount, M.; Wolfe, H. J. *Lab Invest* 40(2): 140-154; 1979.

The histogenesis of medullary thyroid carcinoma (MTC) in the rat was defined, the relationships between the development of this tumor and preexisting C-cell abnormalities at various ages were determined, and the suitability of the rat as a model for human familial MTC was evaluated. MTC is a distinctive neoplasm that is derived from the calcitonin (CT)-producing intrathyroidal C-cell system and develops commonly in untreated rats of various strains. Thyroid glands of Long-Evans rats aged 3 mo-3 yr showed a spectrum of C-cell proliferative abnormalities. Compared with 3-mo-old control rats, thyroids from 9- to 12-mo-old animals exhibited mild, diffuse, C-cell hyperplasia (CCH). Thyroids from animals 1-3 yr of age exhibited progressively more severe C-cell abnormalities, including severe diffuse CCH, nodular CCH, and/or MTC. In contrast to the normal basal serum CT levels in controls and in animals with mild diffuse CCH, animals with severe diffuse CCH, nodular CCH, or

MTC had elevated basal serum CT values. Nodular CCH was characterized by the replacement and enlargement of individual follicles by C cells. Larger foci of nodular CCH were characterized by similar changes in multiple adjacent follicles or by an irregular expansion of individual follicles. MTC was characterized by penetration of the follicular basal lamina by C cells with extension into the adjacent thyroid stroma. In addition to the high incidence of thyroïdal C-cell abnormalities, diffuse and/or nodular parathyroid hyperplasia was common. There was no evidence of chronic renal failure in these animals, and the serum Ca levels were within normal limits. Although the stimulus for the initial C-cell proliferation remains unknown, the appearance of MTC is preceded by relatively prolonged phases of CCH. These findings are essentially identical with those noted in human familial MTC, and they indicate that the rat provides a useful model system for studying the regulation of C-cell proliferation during neoplastic development and progression. (34 refs)

- 79-2846 Multiple Keratoacanthoma.** (Ger) Bonniger, F. (Dermatologische Klinik, Ludwig-Maximilians-Universität München, Frauenlobstrasse 9, D-8000 München 2, W. Germany); Burg, G. *Hautarzt* 30(2): 92-94; 1979.

A 59-yr-old man with a 5-yr history of spontaneously healing multiple keratoacanthomas (MKA) of the head and neck is described. There were no cases of MKA in his family. He had been exposed to tear gas occupationally for 2 yr, 27-28 yr before the onset of the disease. The etiology of MKA is unknown: tar, oil, intensive exposure to sunlight, trauma, and viruses have been reported to be etiological factors. It is not known if the tear gas was an etiological factor in this case. Clinically and histologically, MKA are similar to solitary keratoacanthomas. Transformation of these lesions into squamous cell carcinoma is possible. (27 refs)

- 79-2847 Multiple Tumors Arising in Nevus Sebaceus.** (Eng) Lillis, P. J. (Dept. Dermatology, Univ. Iowa Hosps. and Clinics, Iowa City, IA, 52242); Ceille, R. I. *Cutis* 23(3): 310-314; 1979.

The case of a 43-yr-old woman who had three distinct neoplasms and a nevocellular nevus in a single plaque of nevus sebaceus is presented. The tumors had grown out of a birthmark, a large, brown, hairless spot, on her scalp. The neoplasms were an adenoidal basal cell epithelioma, a pigmented basal cell epithelioma, and syringocystadenoma papilliferum. The multitude of lesions in this patient adds support to the concept of nevus sebaceus arising from a pluripotential primary epithelial germ cell. This case illustrates the importance of close follow-up of nevus sebaceus. (11 refs)

- 79-2848 Ultrastructural and Cytochemical Studies on the Pathogenesis of Primary and Transplanted**

Experimental Brain Tumors in Mice (Meeting Abstract). (Eng) Gregory, T. F. (State Univ. New York at Buffalo, Buffalo, NY). *Diss Abstr Int [B]* 39(9): 4143; 1979. (no refs)

79-2849 Epidermal Hemangioendothelioma. (Rus) Sych, L. I. (No affiliation given); Kalamkaryan, A. A. *Vestn Dermatol Venerol* (2): 27-31; 1979.

A rare temporoparietal hemangioendothelioma occurred in a 67-yr-old man shortly after he had suffered a blow to the site. Abnormal signs were noted within 2-3 days of the trauma. Clinically, the lesion was a red-purple, irregularly shaped tumor with defined borders and ulceration in the center. The dermis in the peripheral zone of the tumor contained numerous vascular cavities lined with large cells that had polymorphic hyperchromatic nuclei. (13 refs)

79-2850 Primary Rhabdomyosarcoma of the Cerebrum. An Ultrastructural Study. (Eng) Yagishita, S. (Div. Pathology, Kanagawa Rehabilitation Center, Nanasawa, Atsugi-Shi, Kanagawa, Japan); Itoh, Y.; Chiba, Y.; Fujino, H. *Acta Neuropathol (Berl)* 45(2): 111-115; 1979.

A case of primary cerebral rhabdomyosarcoma in a 51-yr-old woman is reported. The greater part of a subdural, soft gray, tumor located in the right cerebral hemisphere and attached to the midportion of the falx was removed surgically. A recurrent tumor was removed from the same site < 1 yr later. The two surgical specimens were essentially identical histologically, except that the recurrent tumor was more dedifferentiated than the original one. The tumors were polymorphic, but they were composed mainly of poorly differentiated cells interpreted as rhabdomyoblasts without definite cross-striation. Electron microscopy revealed that these cells were rhabdomyosarcomatous cells with strongly acidophilic perikarya and myofibrillary structures in their cytoplasm. The tumors were not teratomatous, as elements other than myoblastic cells were absent. The rhabdomyosarcoma in this case probably arose from intracranial mesenchymal tissue present in the meninges. (27 refs)

79-2851 Progression of Precancerous Lesions. Development of an Experimental Study System in the Hamster Cheek Pouch (Meeting Abstract). (Eng) Ferguson, J. W. (Dept. Dental Sciences, Univ. Otago, Dunedin, New Zealand). *J Dent Res* 58(Special C): 1214; 1979. (no refs)

79-2852 Symptomatic Epilepsy in Cerebral Metastases. (Ger) Neundorfer, B. (Neurologische Klinik, Universitat Heidelberg, Theodor-Kutzer-Ufer, D-6800 Mannheim 1, W. Germany); Meyer-Wahl, L.; Meyer, J. G. *Munch Med Wochenschr* 121(12): 431-432; 1979.

Causes of epilepsy were analyzed in a series of 411 patients in whom the first attack appeared at > 25 yr of age. Cerebral metastases were identified as the cause of epilepsy in 8/441 patients; they included 3 men and 5 women, av age 57.4 yr (the av age of the entire series was 45 yr). The primary tumor was identified as a bronchial carcinoma in 3 patients, breast carcinoma in 2, melanoma in 1, carcinoma of the sigmoid colon in 1, and carcinoma of the urinary bladder in 1. The metastases were localized to the cerebroparietal region in 7 patients and to the occipital region in 1. (14 refs)

79-2853 Familial Brain Tumour (Letter to Editor). (Eng) Thuwe, I. (Psychiatric Res. Centre, Univ. Goteborg, St. Jorgen's Hosp., S-42203 Hisings Backa, Sweden); Lundstrom, B.; Walinder, J. *Lancet* 1(8114): 504; 1979.

Six confirmed cases and one suspected case of primary cerebral tumor were found in a single family on a Swedish coastal island. There was consanguinity between the parents in only one of the patients, but for every patient the families of both parents could be traced back at least to the 18th century to the same isolated country district. A high proportion of other family members had epilepsy, and several had pathological electroencephalograms, in some cases with focal signs. (no refs)

79-2854 Metastatic Breast Carcinoma in an Intracranial Meningioma. (Fre) Di Bonito, L. (Istituto d'Anatomie et Histologie Pathologique, Ospedale Maggiore, v. Stuparich 1, 34125 Trieste, Italy); Bianchi, C. *Sem Hop Paris* 55(3/4): 171-172; 1979.

A meningioma containing metastatic breast carcinoma tissue was discovered in the left frontal lobe of a 68-yr-old woman who died of progressive breast cancer. Literature studies suggest that the coexistence of meningioma and breast carcinoma is not mere chance. (6 refs)

79-2855 Giant Central Ossifying Fibroma of the Mandible: Report of Case. (Eng) Carlisle, J. E. (Oral and Maxillofacial Surgery Program, Medical Coll. Georgia Sch. Dentistry, Augusta, GA); Hammer, W. B. *J Oral Surg* 37(3): 206-211; 1979.

The occurrence of central ossifying fibroma of the mandible in a 59-yr-old black woman is reported. Central ossifying fibroma is a slowly progressing lesion that is generally asymptomatic until swelling or deformity occurs. Large lesions may outgrow their blood supply and become infected. No hereditary predisposition has been described for this tumor, and its pathogenesis is unclear. The present patient presented with a 1.5-yr history of a progressively enlarging mass that involved the right side of the mandible. The lesion was diag-

nosed as fibrous dysplasia and was treated by partial incision and recontouring. The lesion recurred with signs of persistent infection that could not be controlled by conservative treatment. The diagnosis was changed to giant ossifying fibroma. Surgical resection of the tumor and involved bone was performed, and follow-up examinations have shown no signs of recurrence. There was some evidence of bone regeneration. In general, the prognosis for this tumor is excellent and recurrence after proper treatment is rare. (9 refs)

- 79-2856 Palatal Metastases in Renal Cell Carcinoma.** (Eng) Susan, L. P. (Al-Mashtal, New Baghdad, 20A/23/5, Baghdad, Iraq); Daughtry, J. D.; Stewart, B. H.; Straffon, R. A. *Urology* 13(3): 304-305; 1979.

Two cases of renal cell carcinoma in which the presenting condition was a palatal tumor are reported. The spread of the tumors to the palate was likely due to communication between the vertebral veins and the greater venous plexus of the head. (9 refs)

- 79-2857 Cementoblastoma: Report of Case.** (Eng) Farman, A. G. (Sect. Oral Biology, Dental Coll., Univ. Riyadh, PO Box 5967, Riyadh, Saudi Arabia); Kohler, W. W.; Nortje, C. J.; Van Wyk, C. W. *J Oral Surg* 37(3): 198-203; 1979.

Fifty-five cases of cementoblastoma appearing in the literature and a new case involving a 19-yr-old man are reviewed. Most of the large and expanding lesions were found in persons < 20 yr old, those found in older individuals being generally smaller. Mandibular lesions were greater than threefold more common than maxillary lesions. The most common sign was swelling of the affected area, and the most frequent symptom was low-grade pain, possibly a sequela to concurrent caries. All of the lesions were round, dense, radiopaque masses fused to one or more teeth; the roots of the affected teeth were resorbed to varying degrees. In the present case, the tooth and attached tumor were totally enucleated under general anesthesia. Radiographic and visual inspection of the specimen showed a distinct cartwheel pattern of calcific spokes radiating from the center of the lesion. Postoperative healing was uncomplicated, and there was no evidence of recurrence during a 2-yr follow-up period. There has been no report of a malignant cementoblastoma or of malignant transformation in a benign cementoblastoma. (36 refs)

- 79-2858 Basal Cell Carcinoma in a Hair Transplant Recipient Site.** (Eng) White, J. W. (Dept. Dermatology, Wilford Hall USAF Medical Center, Lackland AFB, TX, 78236). *Cutis* 23(3): 322-325; 1979.

A basal cell carcinoma (BCC) developed in the central scalp

of a 41-yr-old man at the site of a hair transplant plug placed 5 yr previously. The patient presented with a gradually enlarging, painful ulcer of the scalp that had begun 6 mo previously as a pustule with an erythematous border. Histological examination revealed an infiltrating ulcerated BCC in actinic damaged skin contiguous to fibrosis consistent with scar tissue. A foreign body granuloma containing doubly refractile linear particles was noted in the upper dermis lateral to the BCC. The patient had brown hair and eyes, no freckles, and described himself as one who sunburns easily. The transplanted skin (protected by the hair of the occiput for 36 yr) and the intervening scar were exposed to sunlight for only 5 yr. The adjacent scalp was exposed for at least 14 yr. The exposure occurred in a geographic area known for intense exposure occurred in a geographic area known for intense sunlight. Because there was normal skin between the granuloma and the BCC, the former was probably incidental. This case does not answer the question of trauma as the cause of BCC. It is, however, the only skin carcinoma in a person without evidence of past or present premalignant or other malignant skin lesions. It occurred in skin or scar exposed to the sun for only 5 yr, which was probably not enough time to have been the sole cause of cancer. Thus, it is possible that there was a causal relationship between the hair transplantation and BCC in this case. If so, the trauma was more likely a contributory factor than the sole cause of the carcinoma. (15 refs)

- 79-2859 In Vivo studies of Melanoma Cells Cultured With 5-Bromodeoxyuridine (Meeting Abstract).** (Eng) Gyi, K. K. (Georgetown Univ., Washington, DC, 20007); Wrathall, J. R. *In Vitro* 15(3): 197; 1979. (no refs)

- 79-2860 Growth and Metastasis of Human Melanoma Xenografts in the Hamster Host.** (Eng) Richmond, R. E. (Dept. Biological Sciences, Northern Kentucky Univ., Highland Heights, KY, 41076); Morton, D. L. *J Natl Cancer Inst* 62(4): 761-763; 1979.

The growth and metastasis of three human melanoma cell culture lines (UCLASO-M-12, UCLASO-M-7, and WEG-1) following transplantation into the cheek pouches of antilymphocyte serum (ALS)- and irradiation-immunosuppressed hamsters were studied. Tumor nodules were found in the cheek pouches of hamsters receiving any one of these lines, and by 90-100 days, multiple lung metastases were produced in nearly all hamsters. All cheek pouch tumors were identified as malignant melanomas, and the metastatic nodules were histologically identical. One or two animals within each group also developed gross metastases in other organs. Although grossly evident metastases were apparent in the lungs only after 90-100 days, microscopic foci of tumor cells were present within 20-30 days posttransplantation. The metastases may have been due to the biologic aggressiveness of the transplanted tumor cells and to the profound immunosup-

pression in the hosts caused by the combined whole-body irradiation-ALS technique. (10 refs)

- 79-2861 Epidermodysplasia Verruciformis Versus Disseminated Verrucae Planae: Is Epidermodysplasia Verruciformis a Generalized Infection with Wart Virus?** (Eng) Jablonska, S. (Dept. Dermatology, Warsaw Sch. Medicine, 02-008 Warsaw, Koszykowa 82, Poland); Orth, G.; Jarzabek-Chorzelska, M.; Rzeska, G.; Obalek, S.; Glinski, W.; Favre, M.; Croissant, O. *J Invest Dermatol* 72(3): 114-119; 1979.

Ten patients with epidermodysplasia verruciformis (EV) induced by human papilloma virus type 3 (HPV-3) and 10 patients with HPV-3-induced verrucae planae (VP) of long duration were studied to determine whether the two lesions can be distinguished on the basis of clinical, histologic, or immunologic criteria. HPV DNA's isolated from VP-type EV lesions or from the VP flat warts were alike and distinct from those of HPV-1, -2, and -4. The clinical picture was largely the same in the HPV-3-induced EV and VP, the main difference being that the EV cases were more refractory to treatment. The wartlike lesions of EV also resembled VP histologically; both had characteristic vacuolization of the cytoplasm, pyknosis of the nuclei in the upper malpighian and granular layers, and a basketlike appearance of the horny layer. In contrast, the red plaques on the trunks in EV induced by HPV-4 showed pronounced vacuolization of the nuclei in the entire malpighian and granular layers, and nucleoli and granules were prominent. Most EV and VP patients showed depressed, nonspecific, cell-mediated immunity. No malignant conversion was seen in patients infected with HPV-3, whereas it occurred in two patients infected with both HPV-3 and HPV-4. Pigmented plaques were the most important adverse prognostic sign in EV induced by HPV-3. (21 refs)

- 79-2862 Adenocarcinoma of the Larynx.** (Eng) Mal-lonee, M. S. (U.S. Navy, Okinawa, Japan); Maniglia, A. J.; Goodwin, W. J. *Ear Nose Throat J* 58(3): 115-118; 1979.

A 60-yr-old man presented with hoarseness of 2 mo duration and an enlarging, tender left neck mass. He had been treated with 6,000 rads for a T₁N₀M₀ moderately well-differentiated squamous cell carcinoma 2 yr earlier. Indirect laryngoscopy showed edematous left arytenoid cartilage and a sluggish left vocal cord. A granular erythematous lesion was seen in the left ventricle and on the left true vocal cord. Microscopic examination of the specimen obtained after total laryngectomy and left radical neck dissection revealed poorly differentiated adenocarcinoma (AC) of the left true cord. Nine of 41 nodes were also positive for AC. Review of the literature shows that AC of the larynx is rare. There are generally two types: adenoid cystic (cylindroma) and indeterminant. Hoarseness and dyspnea are the most common symptoms of

both. Men are affected more often than women, and both are affected mainly in the fifth to seventh decades. The poor prognosis of laryngeal AC may be due to its tendency toward noncontiguous spread. The adenoid cystic carcinomas tend to spread along nerve sheaths or to metastasize via hematogenous routes. The case reported may be radiation-induced or a second primary tumor. It is also possible that the original tumor was an AC that was misdiagnosed as squamous cell carcinoma. (5 refs)

- 79-2863 Dermoid Cyst of the Lung. A Case Report.** (Fre) Baril, A. (Service d'Anatomie Pathologique, CHU Bellevue, boulevard Pasteur, 42023 Saint-Etienne Cedex, France); Boucheron, S.; Moulin, J.; Abelanet, R. *Arch Anat Cytol Pathol (Paris)* 27(1): 53-57; 1979.

A case of dermoid cyst of the lung in a 38-yr-old woman is reported, and the literature on dermoid cysts is reviewed. The patient was admitted with a persistent pain in the left shoulder that began after a bronchopulmonary episode with cough and mucopurulent expectoration. X-ray studies showed a homogeneous opacity of av density in the left upper lobe of the lung. Bronchial mucosa samples obtained by bronchoscopy showed inflammation, but no abnormal growth or mucosal dysplasia. Aspirated sputum did not show tumor cells. Six months later, the shoulder pain had disappeared, but the cough and mucopurulent sputum persisted. An upper lobe lobectomy was decided upon despite no change in the x-ray picture or any other biological or histological examinations. A mass the size of a small orange was found in the posterior apical segment of the upper lobe, and enlarged lymph nodes were removed from the area of the aorta. The cyst contained hair and abundant sebaceous material. Among the theories on the histogenesis of dermal cysts in nongenital organs, the most likely appears to be that they arise from blastomeres that have not been repressed in embryonal development. Pulmonary sites are rare, with only 28 reported in the literature since 1861. (46 refs)

- 79-2864 In Vitro ³H-Thymidine Uptake by Esophageal Mucosa in Cat Experimental Esophagitis (Meeting Abstract).** (Eng) Livstone, E. (Dept. Medicine, Yale Univ., New Haven, CT); Sheahan, D.; Reinprecht, C.; Contino, C.; Selling, J.; Biancani, P.; McCallum, R. *Gastroenterology* 76(5, part 2): 1187; 1979. (no refs)

- 79-2865 On the Malignant Potential of Acquired Short Esophagus.** (Eng) Menguy, R. (Genesee Hosp., 224 Alexander St., Rochester, NY, 14607). *Arch Surg* 114(3): 260-263; 1979.

Adenocarcinoma developed in an esophagus lined with columnar epithelium (CE) in a 62-yr-old man with eso-

phageal reflux of 10 yr duration. The latter had led to esophageal shortening. In areas with CE, the metaplastic glandular tissue had a variegated appearance ranging from a quiescent CE to severe dysplasia to focal invasive adenocarcinoma. The more severe dysplastic changes were found close to two foci of carcinoma. These two discrete foci suggested that the potential for malignant degeneration inherent in CE complicating long-standing gastroesophageal reflux is high. (12 refs)

- 79-2866 Stomal Polypoid Hypertrophic Gastritis. A Polypoid Gastric Lesion at Gastroenterostomy Site.** (Eng) Koga, S. (Second Dept. Pathology, Faculty of Medicine, Kyushu Univ. 60, 3-1-1, Fukuoka 812, Japan); Watanabe, H.; Enjoji, M. *Cancer* 43(2): 647-657; 1979.

Stomal polyps (gastritis cystica polyposa, GCP) occurring at the gastroenterostomy site in four men were studied, as were the gastrectomy sites in 38 patients with previous gastroenterostomy who had recently undergone resection of the stomach. The GCP lesions were all located on the gastric side of the anastomosis, and they were most conspicuous near the greater curvature. Sessile polypoid protrusions were observed over the gastric mucosa beside the anastomotic stoma. The chief histologic findings were elongation of the gastric pits, hyperplasia and cystic dilation of the pseudopyloric glands, and epithelial invasion of the submucosa. Similar but less severe changes were observed in the mucosal folds adjacent to the polyps. Scar and granulation tissues were seen at the anastomotic junction of the stomach and jejunum. Among the resection patients, 25 showed localized mucosal hypertrophy or thickening at the anastomotic site. In 9/25 patients, the thickened folds were grossly and macroscopically of a polypoid appearance similar to that of GCP but less severe. The GCP lesions might be considered stomal polypoid hypertrophic gastritis due to chronic irritation by the duodenal juice, resulting in a localized hypertrophy of the fundic mucosa at the anastomotic stoma. (21 refs)

- 79-2867 Familial Polyposis Coli: Heterogeneous Polyp Expression in 2 Kindreds.** (Eng) Lynch, H. T. (Dept. Preventive Medicine and Public Health, Creighton Univ. Sch. Medicine, 2500 California St., Omaha, NB, 68178); Lynch, P. M.; Follett, K. L.; Harris, R. E. *J Med Genet* 16(1): 1-7; 1979.

Two extended kindreds are described that show marked variability in the clinical expression of colorectal adenomatous polyps, ranging from the classical presentation of familial polyposis coli (FPC) to the occurrence of only occasional or solitary adenomatous polyps in the colon. In one family, two individuals had diffuse polyposis at very early ages (7 and 10 yr old) and six others (23-72 yr old) had solitary polyps only. Of the patients with solitary polyps, two had associated colonic malignancies (26 and 35 yr old) and another had a

prophylactic colectomy at age 46. In the second family, 5/11 patients with evidence of polyps showed the classical presentation of FPC and the remainder showed marked phenotypic variation. In the absence of reliable markers and/or distinguishing physical signs signifying genotypic status (as in Gardner's syndrome), it may not be possible to discriminate between those patients who may have reduced penetrance of the FPC gene (yet with high colon cancer risk) and the patient who is free of the FPC gene, but has sporadic polyps of an unknown etiology. It is concluded that these data, although limited to only two families, indicate the need for a more careful description of clinical signs, particularly the number, site, and distribution of colon polyps in high-risk patients from families with a tendency to colon cancer and/or classical FPC. (28 refs)

- 79-2868 Probable Parasellar Meningioma in a Pregnant Woman.** (Eng) Manganiello, P. D. (Endocrinology Unit, Dept. Obstetrics and Gynecology, Medical Coll. Georgia, Augusta, GA, 30909); Meltz, R. C.; Andros, G. J. *Obstet Gynecol* 53(3, Suppl): 435-465; 1979.

The case of a 28-yr-old woman who developed a probable intracranial meningioma during the second trimester of her fifth pregnancy is reported. Presenting symptoms were unilateral periorbital edema of the right eye with paralysis of its intrinsic muscles, headaches, and slight thyroid enlargement. A cerebral arteriogram and axial computerized tomography revealed a probable meningioma arising from the cavernous sinus. Her symptoms improved following spontaneous delivery at 34 wk gestation, and by 4 mo after delivery they had disappeared. Arteriograms showed a definite decrease in the size of the tumor mass. A literature search for meningiomas diagnosed during pregnancy revealed only 39 cases reported since 1927. The spatial relationship of these tumors with surrounding structures is important. In tumors located close to the optic or oculomotor nerves, in the orbit, or in the cavernous sinus, only a slight increase in size produces clinical signs. Since meningiomas are highly vascular tumors, the increased vascularity and engorgement of the pregnant patient's vascular supply to the tumor contribute to the symptoms produced by the tumor. Although the tumor mass expands, there is no increased hyperplastic activity. (18 refs)

- 79-2869 Polyps of the Colon after Ureterosigmoidostomy.** (Fre) Fievez, M. (Institut de Morphologie Pathologique, 6270 Lovervall, France); Rubay, J.; Lefevre, P.; de Pierpont, B. *Arch Anat Cytol Pathol (Paris)* 27(1): 40-44; 1979.

Two cases of intestinal polyps that developed at the site of implantation of ureters in the sigmoid colon are reported. The first patient was an adolescent boy who had been born with an exstrophic bladder. At 2 yr of age, a bilateral ureterosigmoidostomy was performed that had to be abandoned at age

9 yr because of recurrent infection; a cutaneous ureterostomy was then performed. Seven years later, a pediculated polyp that was 3 cm in diameter was removed from the sigmoid colon at the site of the ureterostomy. The second patient, an 18-yr-old girl, also was born with an exstrophic bladder. She originally had a sigmoid implantation of the ureters; subsequently, they were moved to the skin and then to a cecal neobladder. Kidney infections were recurrent and the patient finally died of renal insufficiency. At autopsy, two 3-cm-diameter polyps were found in the colon at the sigmoid implantation site. Histologically, the polyps were composed of intestinal glands with large strands of epithelial tissue and nests of von Brunn cells. Numerous areas of metaplastic transformation of transitional epithelium into colonic mucous epithelium were observed. It is suggested that the polyps originated from urothelial cells from the implanted ureters. (23 refs)

- 79-2870 β -Glucuronidase in Schistosomal Intestinal Polypi of the Colon.** (Eng) El-Zoghby, S. M. (Dept. Applied Medical Chemistry, Medical Res. Inst., Alexandria Univ., Alexandria, Egypt); El-Kholy, Z. A.; El-Shrkawy, A.; Rashad, M.; El-Kilany, S.; Abaza, H.; Gawish, Y. S. *Acta Vitaminol Enzymol (Milano)* 32(1/4): 7-11; 1978.

β -Glucuronidase activity was determined in 20 patients with schistosomal polyposis of the large bowel and 10 patients with a normal colon. β -Glucuronidase activity was significantly increased in schistosomal polypi (339-11,615 units) compared with normal mucosa (313-1406 units; 1 unit liberates 1 μ g phenolphthalein in 1 hr at 37 C). No β -glucuronidase activity was detected in schistosoma ova suspensions. Histopathological examinations showed the classical schistosomal granulomatous reaction. There was no evidence of malignant or premalignant changes in any of the 20 bilharzi patients; however, all the patients had excessive mucus in the colon and rectum. It is hypothesized that the increase in the enzymatic activity of these patients may be due to (1) the presence of a great number of different types of WBC in the granulomas of the schistosomal reaction, (2) the presence of excess mucus, which, with its protein content, could activate the enzyme to a great extent, and (3) the liver dysfunction (usually mild) that was found in the patients. It is concluded that there is no proof of a carcinogenic effect of β -glucuronidase activity in the large intestine of patients with schistosomiasis, nor is its increase an indication of malignancy, as is the case in the urinary bladder affected by schistosomiasis. (15 refs)

- 79-2871 Primary Sarcoma of the Diaphragm.** (Ita) Tufano, G. (I Facolta di Medicina e Chirurgia, Universita di Napoli, Naples, Italy). *Rass Int Clin Ter* 58(17): 1191-1200; 1978.

An abdominal tumor was diagnosed preoperatively by x-rays

in a 38-yr-old man who presented with hypochondrial and epigastric pains. A large tumor of the diaphragm was found at laparotomy. The tumor was diagnosed histologically as a spindle cell sarcoma that probably arose from the stroma. (12 refs)

- 79-2872 Peutz-Jeghers Syndrome Associated with Gastrointestinal Carcinoma.** (Eng) Cochet, B. (Clinique Medicale Therapeutique, Hopital Cantonal, CH 1211 Geneva 4, Switzerland); Carrel, J.; Desbaillets, L.; Widgren, S. *Gut* 20(2): 169-175; 1979.

The malignant potential of Peutz-Jeghers hamartomatous polyps, generally considered benign, is illustrated by two familial cases. Metastasizing gastrointestinal carcinomas associated with the syndrome developed in a 56-yr-old woman and her 29-yr-old son. Both mother and son died from duodenal and gastric carcinomas, respectively, which developed in hamartomatous polyps with extensive metastases. In both cases, there were dysplastic areas within the polyps. These features indicate that hamartomatous polyps may, in some cases, be precursors of digestive tract carcinomas. (19 refs)

- 79-2873 Defining the Precursor Tissue of Ordinary Large Bowel Carcinoma: Implications for Cancer Prevention.** (Eng) Lane, N. (Div. Surgical Pathology, Dept. Surgery, Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Fenoglio, C. M.; Kaye, G. I.; Pascal, R. R. In: *Gastrointestinal Tract Cancer*. Lipkin, M.; Good, R. A., eds. (New York, London: Plenum Medical Book Co.) Sloan Kettering Inst. Cancer Series 602 pp.; 295-324; 1978.

In this attempt to define the precursor (precancerous, or preneoplastic) tissue of ordinary large-bowel carcinoma (Ca), only those benign proliferations known as adenomas (AN's) and hyperplastic polyps (HP's) and only ordinary moderately and well-differentiated adenocarcinomas were considered. HP's have no statistically significant relationship as a precursor tissue to Ca or AN; nonetheless, they are frequently found in colons bearing AN and/or Ca as anatomically separate lesions. In contrast to HP's, several statistical correlations can be noted among the size, shape, and histological patterns of AN's. The av small AN (1-1.5 cm) tends to be pedunculated and to have a tubular pattern. Among larger AN's, a greater proportion tend to be sessile and to have a papillary (villous) pattern. HP's are 10 times as common as AN's and, in turn, small AN's are 10 times as common as large AN's; therefore, the latter constitute only about 1% of all benign proliferations being considered. Ca, intramucosal and invasive, can occur in small AN's, but only the large AN's will harbor invasive Ca with significant frequency ($\geq 10\%$). The likelihood of Ca increases with AN size plus the tendency of larger AN's to be sessile and have papillary features. The cellular origin of Ca involves minute or microscopic dimensions. A

small lesion, to be acceptable as representing the morphology of a neoplasm at its inception, would not be more than a few millimeters or even a fraction of a millimeter in size. Minute or microcancer has been observed in adenomatous tissue but has not been reported as a de novo process in normal mucosa, in spite of unlimited opportunity to find it. De novo Ca also does not seem to occur in familial polyposis, even though there is a tremendous predilection for Ca in this condition. Evidence from a 25-yr clinical study also supports the contention that most ordinary colon adenocarcinoma arises from adenomatous tissue. (19 refs)

- 79-2874 Familial Polyposis Coli.** (Eng) Bussey, H. J. (St. Mark's Hosp., London, England); Morson, B. C. In: *Gastrointestinal Tract Cancer*. Lipkin, M.; Good, R. A., eds. (New York, London: Plenum Medical Book Co.): Sloan Kettering Inst. Cancer Series 602 pp.; pp. 275-294; 1978.

The sex and age distribution, symptoms, inheritance, incidence in the general population, diagnosis, histology, treatment, relation with malignancy, and similarity to Gardner's syndrome of familial polyposis coli (FPC) are reviewed. There is an equal sex distribution, and the average age at diagnosis is 35. Rectal bleeding is the most common symptom, and the disease is characterized by the presence of hundreds or thousands of adenomatous tumors in the colon and rectum. It is now firmly established that the lesions are genetic in origin, most victims having inherited the disease from an affected parent. There is a high incidence of intestinal carcinoma in FPC patients, and the incidence is particularly high in patients with untreated disease. The evidence suggests that colorectal cancer arises in preexisting adenomas. Several recent reports suggest that all FPC may be Gardner's syndrome with varying degrees of expressivity. FPC is a useful model for study of the development of adenoma and carcinoma in the large intestine. The adenomas in FPC are indistinguishable from those found more generally in the nonpolyposis population; adenomas from both sources can show progressively increasing epithelial atypia that finally equates with that seen in invasive carcinoma. The disease is also closely associated with other growth patterns, mostly of a neoplastic nature, some benign and some malignant. (27 refs)

- 79-2875 Five Cases of Leiomyosarcoma of the Small Intestine.** (Jpn) Terada, K. (Dept. Surgery, Kochi Prefectural Central Hosp., Kochi, Japan); Kondo, K.; Hashimoto, T.; Iwata, K.; Nishiyama, A.; Hisano, K. *Gan No Rinsho* 25(2): 143-147; 1979.

The case reports of five patients (3 men, 2 women aged 45-59 yr) with small intestinal leiomyosarcoma are presented. One of the tumors was in the duodenum and four were in the jejunum; all five tumors showed exophytic growth. One pa-

tient had metastatic foci in the liver, one had massive metastases to the liver, and the third had massive metastases to the liver, peritoneum, and lymph nodes. (10 refs)

- 79-2876 Vagotomy and Gastric Cancer.** (Hun) Gombkoto, B. (Sebeszeti es Urologiai Osztaly, Megyei Korhaz, Eger, Hungary); Tasi, I. *Orv Hetil* 120(5): 259-264; 1979.

Gastric carcinoma was found in two patients who had undergone vagotomy. Selective vagotomy was performed for duodenal ulcer in a 57-yr-old woman. A partly mucocellular scirrhous carcinoma of the stomach was diagnosed 5 yr later. Truncal vagotomy was performed in a 52-yr-old man 8 yr after Billroth-II gastric resection for duodenal ulcer. A partly medullary adenocarcinoma of the gastric stump was found 16 yr after the vagotomy. The findings suggest that there is a possible relationship between vagotomy and gastric cancer. (44 refs)

- 79-2877 Patterns of Tumor Cell Aggregation and Metastasis in Scirrhous Carcinoma of the Stomach, Borrmann Type IV.** (Jpn) Kodama, Y. (Dept. Surgery II, Kyushu Univ. Sch. Medicine, Fukuoka 812, Japan); Inokuchi, K. *Gan No Rinsho* 25(2): 89-93; 1979.

The patterns of tumor cell aggregation and metastasis in 43 patients with Borrmann Type IV scirrhous carcinoma of the stomach were investigated. Of the 24 patients with lymphatic involvement, 21 showed small nest-type aggregation (SNA) and 3 showed free cell aggregation (FCA). Tumor cell aggregation in the 29 patients with lymph node involvement was of the nest type in 22 and the free cell type in 7. Lymphatic involvement in the submucosal layer (19/24) and serosa (9/24) was most common. Transitional cancer cells occurred in all 29 patients with lymph node involvement, with 24% showing FCA and 76% SNA. FCA was mainly associated with low levels of lymph node transition and lymphatic infiltration, SNA with higher levels. SNA was associated with low to moderate degrees of fibrosis in the submucosal layers of the stomach wall, FCA with moderate to high degrees of fibrosis. Free cells in the mucosal layer infiltrated diffusely into the interstitium with little lymphogenous spread, but small nests of cells were accompanied by frequent lymphogenous spread. (5 refs)

- 79-2878 The Viability of Free Cancer Cells in the Peritoneum of Patients with Gastric Cancer.** (Jpn) Tanida, O. (First Dept. Surgery, Tottori Univ. Sch. Medicine, Yonago-shi 683, Japan); Takeuchi, T.; Kaneshima, S.; Iit-suka, Y.; Sasaki, Y.; Koga, S. *Gan No Rinsho* 25(2): 101-106; 1979.

Changes in the morphology and viability of free cancer cells

in the peritoneum of 10 stomach cancer patients were evaluated by enzymological staining, Giemsa staining, and autoradiography with ^3H -thymidine. The patients were six men and four women aged 41-69 yr. After abdominal incision but before surgery, 150 ml warm culture fluid were injected into the area of Douglas' space and then collected immediately and stained. A second sample was taken from the same area by the smear method and stained. The free cancer cells showed moderate degeneration but high viability. Cancer cells on the gastric serosa also showed high viability. Thus, the implantation and proliferation of free cancer cells on the peritoneum is possible. Ip injection of 10 mg mitomycin C (MMC) markedly decreased the viability of the free cells in Douglas' space. Ip injection of MMC after gastric surgery was judged to be an effective method of preventing the peritoneal dissemination of cancer cells. (13 refs)

- 79-2879 Malignant Change of Juvenile Polyp of Colon: A Case Report.** (Eng) Tung-hua, L. (Capital Hosp., Chinese Acad. Medical Sciences, Peking, China); Min-chang, C.; Hsien-chiu, T.; Lan, C.; Chieh, L. *Chinese Medical J* 4(6): 434-439; 1978.

Malignant change of a juvenile polyp of the descending colon (near the splenic flexure) occurred in a 16-yr-old boy. The pathologic diagnosis was malignant change of a juvenile polyp of the descending colon into a signet ring cell carcinoma with tumor thrombi in the lymphatics and blood vessels. A review of the world literature on juvenile polyps over the past 20 yr failed to reveal any report indicating that this condition is precancerous or potentially malignant. However, the present case is believed to be a typical one of juvenile polyp undergoing malignant change because the carcinoma developed entirely within the polyp. Its pedicle and the surrounding colonic wall were devoid of cancer. (12 refs)

- 79-2880 Anabolic Steroid Therapy and Intrahepatic Cholangiocarcinoma.** (Eng) Stromeyer, F. W. (Hepatic Pathology Dept., Armed Forces Inst. Pathology, Washington, DC, 20306); Smith, D. H.; Ishak, K. G. *Cancer* 43(2): 440-443; 1979.

The case of a 47-yr-old man who developed a cholangiocarcinoma 3 yr following the commencement of anabolic steroid (oxymetholone) therapy for refractory hypoplastic anemia is reported. The tumor showed mucin production and was devoid of hepatocellular elements; there were metastases to the lungs and abdominal lymph nodes. Previous reports have suggested a possible relationship between anabolic steroid therapy and hepatocellular carcinoma. However, in many of these cases there are doubts concerning the histologic diagnosis, malignant potential, or nature of the association between steroid therapy and tumor. Although a causative relationship between the steroid therapy and tumor in the present case is not established, the case does suggest that intrahepatic cho-

langiocarcinoma should be included among the group of hepatic lesions possibly related to anabolic steroid therapy. (35 refs)

- 79-2881 Spontaneous Liver Tumors in Aged Germfree Wistar Rats.** (Eng) Pollard, M. (Lobund Lab., Univ. Notre Dame, Notre Dame, IN, 46556); Luckert, P. H. *Lab Anim Sci* 29(1): 74-77; 1979.

The incidence of spontaneous liver tumors in 132 germfree Lobund Wistar rats aged > 30 mo was studied. A total of 115 of these rats (76/90 males and 39/42 females) had 5-20 tumors per liver. In addition, three rats had cystic lesions and two showed extensive necrosis in their livers. A wide range of histologic changes was observed; 11 rats had changes compatible with a diagnosis of hepatocellular carcinoma. No clearly defined liver cirrhosis or metastatic lesions were observed. Large numbers of rats also developed benign adenomas of the pituitary, thymus, breast, adrenal cortex and medulla, parathyroid, and thyroid. Similar benign tumors were observed in germfree rats aged 20-29 mo, and benign liver neoplasms were observed in 16/70 males and 2/22 females. Liver lesions were observed among relatively few of the 200 conventional Wistar rats examined up to 25 mo of age; few of these animals lived as long as 30 mo. The etiology of the liver lesions in the aged germfree rats is not known. (17 refs)

- 79-2882 Atypical Carcinoma of Kidney. Possibly Originating from Collecting Duct Epithelium.** (Eng) Cromie, W. J. (Dept. Urology, National Naval Medical Center, Bethesda, MD, 20014); Davis, C. J.; DeTure, F. A. *Urology* 13(3): 315-317; 1979.

A case of atypical renal carcinoma showed cellular elements of both renal cell and transitional cell carcinoma. The unusual histologic features suggest that the tumor originated in the collecting duct epithelium. (10 refs)

- 79-2883 Childhood Cancer and the SBLA Syndrome.** (Eng) Lynch, H. T. (Dept. Preventive Medicine/Public Health, Creighton Univ., Omaha, NB, 68178); Guirgis, H. A. *Med Hypotheses* 5(1): 15-22; 1979.

Two kindreds manifest a syndrome characterized by a hereditary predisposition to sarcoma (S), brain tumors and breast cancer (B), leukemia, lymphoma, and laryngeal and lung cancer (L), and adrenal cortical carcinoma (A), known as the SBLA syndrome, are described. In these two nuclear families the progeny of breast cancer-affected mothers manifested early childhood malignant neoplasms. These observations have led to the development of a genetic-environmental interactive model that incorporates Knudsen's two-hit hypothesis as a

partial explanation for the exceedingly early onset of cancer in the progeny. Given the assumption that the first hit was germinal with transfer of the deleterious SBLA gene at conception, it is postulated that the second or somatic hit occurred early in utero. For example, it is likely that the rhabdomyosarcomas occurring in progeny of one family and the adrenal cortical carcinoma occurring in progeny of the second family most probably had their origins in utero. Given the chronology of the tumor occurrences, the mothers from the families must have manifested occult carcinoma of the breast while their cancer-affected fetuses were developing. This hypothesis provides a rational explanation for the interaction of the SBLA genotype (first hit) and other etiologic events (putative oncogenic virus, a derepressed oncogene, and tumor-specific antigens) that may have crossed the placenta and contributed to cancer in the fetus (second hit). This theory is based on the supposition that the mothers had already sustained both hits (germinal and somatic) and that their fetuses received the germinal hit at conception but sustained the second hit transplacentally. (16 refs)

79-2884 The Problem of Carcinoma Developing in a Fibroadenoma. Recent Experience at Memorial Hospital. (Eng) Fondo, E. Y. (135 E. 71st St., New York, NY, 10021); Rosen, P. P.; Fracchia, A. A.; Urban, J. A. *Cancer* 43(2): 563-567; 1979.

Fourteen new cases of unsuspected carcinoma developing in fibroadenomas are reported. The patients averaged 42 yr of age at the time of diagnosis, and four had a previous history of exogenous hormone usage. Mammography revealed an abnormality in two-thirds of the cases. The microscopic appearance was similar to that of carcinoma unassociated with fibroadenoma. Twelve patients had noninvasive carcinoma, one had intraductal and infiltrating duct carcinoma, and one had intraductal carcinoma in the fibroadenoma and infiltrating carcinoma in the adjacent breast parenchyma. The fibroadenomas involved by carcinoma generally showed a fairly abundant benign epithelial component, but there was no evidence of striking or unusual epithelial hyperplasia in the breast tissue adjacent to the carcinoma-containing fibroadenomas. Four of the 14 patients also had carcinoma in the contralateral breast, the bilateral disease being synchronous in 2 patients. All patients are alive and clinically free of disease following treatment (local excision in 3 patients, mastectomy in 11). Contralateral breast biopsy at the time of diagnosis with a careful lifetime follow-up are appropriate because of the high risk of contralateral invasive carcinoma. (11 refs)

79-2885 Detection of Asymptomatic Breast Cancer in the Second Breast by Mammographic Follow-Up: A 5-Year Survey. (Eng) Rosner, D. (Dept. Breast Surgery, Roswell Park Memorial Inst., Buffalo, NY, 14263); Nemoto, T.; Dao, T. L. *Prev Det Cancer Part II Vol I* 1281-1285; 1978.

The detection of asymptomatic cancer in the other breast by routine periodic mammography was analyzed among 408 women who had previously undergone one mastectomy for carcinoma. A total of 221 patients were followed for 2-5 yr (av 3 mammography studies/patient); the remaining 187 were followed for a relatively short time (1-2 studies/patient). Mammography demonstrated abnormalities in 50 patients. Biopsy of the suspicious area in 31 of these patients revealed carcinoma in 12 and various benign lesions in 19. Mammographic findings in the 12 carcinoma patients were a mass in 5, a cluster of calcifications in 3, and a mass with calcifications in 4. Nine patients had invasive carcinomas, (2 lobular and 7 adenocarcinomas) and 3 had in situ lobular carcinomas. Positive axillary nodes were found in only 1/7 patients who underwent mastectomy for invasive carcinoma. Two patients who did not undergo biopsy in spite of abnormal mammographic findings developed clinically apparent carcinomas 12 and 24 mo later. During the study period, eight breast cancers were discovered by clinical examinations prior to mammography. The tumor size was larger in this group, and all had axillary nodal metastasis. Four are free of disease, one is living with metastasis, and three died of metastatic disease. Among the nine patients whose invasive carcinomas were detected by mammography, seven are free of disease and two died. (12 refs)

79-2886 Adenocarcinoma of the Vagina in a Patient with Gonadal Dysgenesis. (Eng) Shingleton, H. M. (Dept. Obstetrics and Gynecology, Univ. Alabama, University Station, Birmingham, AL, 35294); Younger, J. B.; Beasley, W. E.; Levy, D.; Gore, H.; Lawrence, W. D. *Obstet Gynecol* 53(3, Suppl): 925-975; 1979.

A case of adenocarcinoma of the vagina in a 21-yr-old black woman with gonadal dysgenesis is presented. The tumor contained papillary areas and areas of adenocarcinoma with small gland spaces. In the papillary areas, the cytoplasm was scanty and pale-staining, forming a 'hobnail' pattern. The histologic pattern suggested derivation from the paramesonephros. Evidence of mucin production by the tumor also favored a paramesonephric origin, as did the absence of fat in the electron micrograph. Electron microscopy identified two cell populations: pale-staining (light) cells that were large and polygonal with short, stubby microvilli on the luminal surfaces; and dark cells, which were seen less frequently and were smaller than the light cells. The light cells resembled those seen in a previously reported vaginal clear cell diethylstilbestrol-related adenocarcinoma with respect to basal-located lysosomes of unusual shape, high metabolic activity, and abundant glycogen and granular endoplasmic reticulum. The development of vaginal adenocarcinoma in this patient is unique in that she had no exogenous estrogen influence antenatally and an estrogen deficiency postnatally. (19 refs)

79-2887 Granulosa Cell Deficient Follicles. Occurrence, Structure, and Relationship to Ovarian Terato-

carcinogenesis in Strain LT/Sv Mice. (Eng) Eppig, J. J. (Jackson Lab., Bar Harbor, ME, 04609). *Differentiation* 12(2): 111-120; 1978.

A comparison study was made of the diameters of oocytes in follicles having a single layer of granulosa cells (GC's) in 4-wk-old LT/Sv mice and in mice of various common strains. There is a unique population of these follicles in strains LT/Sv and C58/J in which the oocytes are significantly larger than the oocytes in single GC-layered follicles of other common strains (C57BL/6J, BALB/cJ, and DBA/2J). These unique follicles are referred to as GC-deficient (GCD) follicles, since oocytes of these sizes are usually found in follicles with more than a single layer of GC's. The parthenogenetic embryos that give rise to ovarian teratomas in strain LT/Sv are usually found in GCD follicles. Some of the ova of strains LT/Sv and LTXBP, but not the ova of the other strains, are capable of spontaneous parthenogenetic activation after meiotic maturation. Although the ovulated ova of strain LTXBP are capable of spontaneous parthenogenetic development, the frequency of GCD follicles and teratocarcinogenesis is low. Therefore, the frequency of ovarian teratocarcinogenesis is correlated with the simultaneous occurrence of two atypical conditions: (1) the capability of the matured ova to undergo spontaneous parthenogenetic activation and, (2) the high frequency of GCD follicles. GCD follicles containing oocytes with a diameter $> 65 \mu\text{m}$ were studied by electron microscopy. The follicles are usually enclosed within a layer of flattened thecalike cells. A basal lamina separates these cells from a single layer of cuboidal GC's. GC processes traverse the zone pellucida to contact the oocyte, which shows ultrastructural characteristics typical of oocytes in the final growth stages. It is proposed that the GCD follicles are competent to participate in the normal functions of follicular cells relating to oocyte growth and meiotic maturation. (13 refs)

79-2888 Primary Pure Insular Ovarian Carcinoids. (Eng) Holtz, G. (9 Duffy St., Charlestown, SC, 29407); Tucker, E.; Holtz, F. *Obstet Gynecol* 53(3, Suppl): 855-875; 1979.

The 23rd and 24th literature cases of primary pure insular ovarian carcinoids are presented. One of the patients, a 66-yr-old woman, presented initially with carcinoid heart disease. Severe tricuspid insufficiency, pulmonary stenosis, and mild aortic insufficiency were documented. A unilateral salpingo-oophorectomy (S-OP) was performed. Argentaffin reaction was positive. The second case was seen in a 46-yr-old woman who presented with complaints of urinary incontinence and frequency. This patient underwent a total abdominal hysterectomy and bilateral S-OP. Argentaffin reaction was weakly positive. No teratomatous elements or evidence of luteinization was seen in either patient. If the diagnosis of carcinoid syndrome in the absence of hepatic involvement is made, an extensive search should be made for lesions other than an ovarian primary. This must include a search for non-

carcinoid malignant lesions that may present with the carcinoid syndrome. Most of these tumors behave in a benign manner, with only three cases of documented metastases being reported. In view of this, unilateral S-OP is adequate therapy for the premenopausal patient if the opposite ovary is normal. Postoperatively, patients should be followed with serial 5-hydroxyindolacetic acid determinations, with any rise being diagnostic of recurrence. (10 refs)

79-2889 A Histologic Study of Ovarian Endometriosis with Emphasis on Hyperplastic and Atypical Changes. (Eng) Czernobilsky, B. (Dept. Pathology, Kaplan Hosp., Rehovot, Israel); Morris, W. J. *Obstet Gynecol* 53(3): 318-323; 1979.

The histologic features of ovarian endometriosis were studied in 194 affected patients seen over a 3-yr period (1972-1974). The mean age was 38.3 yr, and 181 patients were white and 13 were black. The lesions were bilateral in 42 patients, localized in the left ovary in 88, and localized in the right ovary in 64. All patients had endometrial-type epithelium and stroma. Ovarian-type epithelium was demonstrated in 26 patients, papillary epithelial-lined projections in 7, and hobnail cells in 36. Reactive epithelial changes were observed in 43 patients, and this feature was usually associated with severe stromal inflammation and areas of epithelial denudation and regeneration. Severe epithelial atypism and degenerative changes were present within the cyst linings of seven patients. In two of these patients, severely atypical changes were also observed within glandular structures; in three, stromal inflammation was present underneath the epithelium. Adenomatous hyperplasia was seen in one of these patients as well as in four other patients. Although the areas of severe epithelial atypism in ovarian endometriosis may be of reactive origin, the possibility that in some instances these changes may have a neoplastic potential must be considered. (15 refs)

79-2890 Adenocarcinoma of the Endometrium in Pregnancy. (Eng) Sandstrom, R. E. (James Homer Wright Pathology Labs., Massachusetts General Hosp., Boston, MA); Welch, W. R.; Green, T. H. *Obstet Gynecol* 53(3, Suppl): 735-765; 1979.

The seventh case of endometrial adenocarcinoma coexistent with an intrauterine pregnancy is reported. This case is believed to be the first noted as an incidental finding in therapeutic abortion. Because microscopical examination of the uterine contents of the patient, a 37-yr-old woman, revealed foci of well-differentiated adenoacanthoma in addition to products of conception, a hysterectomy and bilateral salpingo-oophorectomy were performed 3 wk later. All seven patients were white and were 21-43 yr old. Most complained of dysmenorrhea, irregular menses, or hypermenorrhea of recent onset and short duration. Five patients were multiparous, two nulliparous. Only one had a history of previous

estrogen therapy, and that was only for a short period. Except for obesity, constitutional factors associated with endometrial carcinoma (EC) were not reported. The tumor was limited to a small focus in four cases. Four of the neoplasms were adenoacanthomas, tumors that account for only 20%-30% of the endometrial adenocarcinomas in the general population. The one patient who died had an adenoacanthoma and was the only patient with extensive myometrial invasion at hysterectomy. The apparent rarity of EC in association with pregnancy may be related to several factors: EC generally occurs in the postmenopausal period; patients prone to EC are, as a group, less fertile; the hormonal milieu of pregnancy with high progesterone levels may be unfavorable for tumor survival. (15 refs)

- 79-2891 Massive Necrosis of Uterine Leiomyoma Following Administration of a Single Dose of Medroxyprogesterone.** (Spa) Molina, R. (Servicio de Ginecología, Hospital General del Sur, Maracaibo, Venezuela); Torres, R. *Invest Clin (Maracaibo)* 19(2): 62-67; 1978.

A 37-yr-old woman with an unremarkable gynecological history developed acute abdomen approx 2 wk after she was inoculated with a single 150-mg dose of medroxyprogesterone acetate for contraception. Peritonitis and uterine myoma were diagnosed. Total hysterectomy was performed after symptomatic treatment. Nearly complete necrotic uterine leiomyomas were found. The acute abdomen was due to the tumor necrosis. The patient has been symptom-free 3 yr after surgery. (7 refs)

- 79-2892 Carcinoid of the Uterine Cervix. A Case Report with Light and Electron Microscopic Studies.** (Eng) Habib, A. (Dept. Pathology, Mt. Sinai Sch. Medicine, City Univ. New York, 100th St. and Fifth Ave., New York, NY, 10029); Kaneko, M.; Cohen, C. J.; Walker, G. *Cancer* 43(2): 535-538; 1979.

The case of a 33-yr-old woman with primary carcinoid of the uterine cervix is reported. The woman had had three pregnancies, one of which ended in abortion. A radical Wertheim hysterectomy with bilateral pelvic lymphadenectomy, aortic lymphadenectomy, and right salpingo-oophorectomy was performed. There has been no evidence of recurrent disease in the 2.5 mo since surgery. Microscopic examination of the cervix revealed a tumor forming solid nests, trabeculae, and glands. The tumor infiltrated the entire thickness of the cervical wall, but it did not extend to the parametria or exocervical margin. Several lymphatics contained tumor cells. The tumor cells showed argyrophil granules, but they were negative for the argentaffin reaction. Electron microscopy revealed the presence of numerous neurosecretory granules and microfilaments. The tumor was classified as a well-differentiated carcinoid of the uterine cervix. Carcinoid of the uterine cervix is a distinct tumor entity and should be distinguished from

the more common epidermoid and adenocarcinoma variants. (26 refs)

- 79-2893 Morphogenesis of Cervical Carcinoma.** (Rus) Murav'ev, G. N. (Rest. Inst. Oncology and Medical Radiology, Minsk, USSR). *Vopr Onkol* 25(2): 13-19; 1979.

The diagnostic efficacy of alterations in the stroma of the cervix uteri for distinguishing between proliferative or dysplastic changes and preinvasive or early carcinoma was evaluated. Surgery and biopsy specimens were obtained from 30 patients with inflammatory processes, 60 with endocervicitis, 20 with erosions, 30 with ectropion, 125 with erosions plus epidermization and dysplasia, 57 with leukoplakias plus dysplasia, 180 with preinvasive intraepithelial carcinoma, 40 with Stage I carcinoma, 30 with Stage II carcinoma, and 20 with Stage III carcinoma. Patients with inflammations but without proliferation of the epithelium featured various changes in stroma structure; these changes were confined to the site of the pathologic focus. Progression of tumor development was associated with the appearance of acid mucopolysaccharides, increased vascularization, edema, and expansion of the boundaries of the tumor field. The rate of stromal and vascular changes correlated with the boundaries of the tumor field. (11 refs)

- 79-2894 The Basement Membrane in Experimentally Induced Atypias and Carcinoma of the Uterine Cervix in Mice. An Immunofluorescence Study.** (Eng) Rubio, C. A. (Dept. Pathology, Karolinska Sjukhuset, S-10401 Stockholm 60, Sweden); Biberfeld, P. *Virchows Arch [Pathol Anat]* 381(2): 205-209; 1979.

Basement membrane-specific antigens of the squamous epithelium of the uterine cervix were investigated in 19 normal C57Bl mice, in 7 mice with cervical atypia, and in 3 mice with invasive carcinoma. Cervical atypia and carcinoma were induced by local application of 1% benzo(a)pyrene in acetone. Basement membrane-specific antigens were demonstrated by immunofluorescence with sera from patients with bullous pemphigoid. Both normal squamous cervical epithelium and atypical cervical epithelium showed the presence of a continuous, clearly delineated basement membrane. Clusters of invasive squamous carcinoma were also surrounded by a fluorescent basement membrane, but it appeared fragmented or discontinuous. The results suggest that the ability of cervical squamous cells to secrete basement membrane antigens is not completely lost during carcinogenesis, thus substantiating previous observations in the human cervix. (16 refs)

- 79-2895 Germ Cell Neoplasms Arising in Gonadoblastomas.** (Eng) Hart, W. R. (Dept. Pathology, Univ. Michigan Medical Sch., 1335 E. Catherine St., Ann

Arbor, MI, 48109); Burkons, D. M. *Cancer* 43(2): 669-678; 1979.

The clinicopathologic findings in six phenotypic women with features of 46, XY pure gonadal dysgenesis who developed germinomas and other germ cell tumors in gonadoblastomas are reported. All stages in the evolution of germinoma from the germ cells of gonadoblastoma were observed. The earliest form corresponded to in situ germinoma, in which the nests of gonadoblastoma became distended with a monotonous proliferation of neoplastic germ cells. In the next phase, clusters of infiltrating cells coalesced to form a small nodule of microinvasive germinoma without producing a sizeable mass. Metastases have not yet occurred postoperatively in the two patients with these incipient microinvasive forms. Larger invasive germinomas occurred in four patients, two having pure germinomas and two having germinomas mixed with either mature teratoma or endodermal sinus tumor. Two of these tumors were complicated by metastatic spread to the lymph nodes, but moderate dosage radiation therapy resulted in long-term survival and probably cure in at least one of these patients. Although it is debatable whether gonadoblastomas are true neoplasms or blastomatoid dysgenetic malformations, they have the same malignant potential as tumors that arise de novo in the gonad or extragonadal sites. They also appear to have the same overall favorable prognosis and radiosensitivity as de novo ovarian germinomas. (15 refs)

79-2896 Testicular Tumor: Report of Three Familial Cases. (Eng) Lowe, W. C. (Dept. Medicine, Veterans Admin. Hosp., East Orange, NJ); Akgun, S. *Cancer Detect Prev* 2(1): 75-82; 1979.

The occurrence of malignant testicular neoplasms (TN) in two brothers and their nephew is reported. One brother was admitted at age 44 with a 5- x 5-cm mass in the right scrotum and a 6- x 6-cm mass in the right lower abdomen. All laboratory data were normal except for a lactic dehydrogenase level of 1,800 units. After radical orchiectomy (Or-x), histological section showed a mixed tumor consisting of seminoma and embryonal cell elements. His nontwin brother noted gradual enlargement of the right scrotum at age 23. He underwent right radical Or-x 1 yr later for testicular teratocarcinoma. A 16-yr-old nephew of the brothers noted a small mass in his right testis that eventually became painful. Histologic section after right Or-x showed embryonal cell carcinoma with choriocarcinoma elements. According to a review of the literature, malignant TN are rare. Most familial cases are in the age group 20-40. Cryptorchism and trauma to the testis are often associated with TN, although they had not occurred in the three reported patients. It is relatively easy to demonstrate that TN are probably genetically determined in experimental animals, but not in men. However, studies of the number of chromosomes in human TN showed that hyperdiploid, -triploid, and -tetraploid tumors were common. In a study of TN by the quinacrine fluorescence technique, all were found to contain a Y chromosome. This report of multiple TN in one family supports the hypothesis that these neoplasms are determined partly by genetic susceptibility. (32 refs)

79-2897 Mixed Brenner and Adenomatoid Tumor of the Testis. An Ultrastructural Study and Histogenetic Considerations. (Eng) Nogales, F. F. (Hospital Universitario, Avda, Spain); Matilla, A.; Ortega, I.; Alvarez, T. *Cancer* 43(2): 539-543; 1979.

The association of Brenner and adenomatoid tumor in the tunica vaginalis testis of a 37-yr-old man is reported. The adenomatoid tumor was the predominant pattern. Intimately admixed and randomly situated within it were numerous Brenner nests separated from the surrounding fibroblasts by a well-developed basal lamina. Ultrastructurally, both neoplastic patterns were evident, and they shared some, but not all, features. The shared features included intracellular spaces lined by cytoplasmic projections, deeply indented nuclei, tight desmosomal contacts, and cytoplasmic microfilaments. The fact that both tumors arose from the tunica vaginalis, coupled with their many ultrastructural similarities and intimate association, suggests that both were of mesothelial origin. (15 refs)

79-2898 Characteristics of Cell Cultures Derived From Hyperplastic Hemal Nodes (Meeting Abstract). (Eng) Amborski, G. F. (Louisiana State Univ., Sch. Veterinary Medicine, Baton Rouge, LA, 70803); Amborski, R. L.; Seger, C. L. *In Vitro* 15(3): 196; 1979. (no refs)

EPIDEMIOLOGY AND BIOMETRY

- 79-2900 Pregnancy, Breast-Cancer Risk and Maternal-Fetal Genetics (Letter to Editor).** (Eng) Doll, R. (Dept. Regius Professor Medicine, Radcliffe Infirmary, Oxford, England). *Lancet* 1(8115): 559; 1979.

An alternative explanation for the observation that the proportion of women who are single is less among those with breast cancer (BC) than among those with other types of cancer (OC) between 20 and 24 yr of age is given. At young ages the marriage rate is appreciable. The incidence of BC under 40 yr of age increases more rapidly with age than the incidence of OC. The proportion of BC patients who are single will be less than that of patients with OC when women of marriageable age are grouped together in 5-yr age groups. As the marriage rate declines, this effect gradually disappears, until the greater incidence among single women becomes evident. (1 ref)

- 79-2901 Histologic Comparison of Mammary Carcinomas among a Population of Southwestern American Indian, Spanish American, and Anglo Women.** (Eng) Black, W. C. (Cancer Res. and Treatment Center, Univ. New Mexico, 900 Camino De Salud, N. E., Albuquerque, NM, 87131); Bordin, G. M.; Varsa, E. W.; Herman, D. *Am J Clin Pathol* 71(2): 142-145; 1979.

Primary carcinomas of the breast were studied in age-matched New Mexican women of Southwestern American Indian, Spanish American, and Anglo ancestry. The women were from an area served by the New Mexico Tumor Registry. The principal tumor pattern in each group was infiltrating ductal carcinoma. The remaining histologic tumor types were similar except for an increased frequency of lobular carcinoma among the Anglo women compared with the other groups. The carcinomas had an irregular, stellate pattern (as opposed to a circumscribed pattern) in 36/45 Indian patients, 39/45 Spanish American patients, and 36/45 Anglo patients. The nuclear grade was most often I among the Indian women and most often II among the other groups. The cellular inflammatory response to tumor was generally absent-to-negligible or slight-to-moderate in all groups. Intraductal carcinoma was present within the substance or margin of the tumors in 23 Indian women, 23 Spanish American women, and 31 Anglo women. Indian women presented with a less favorable tumor stage at diagnosis compared with the other groups. The data do not demonstrate clearly defined differences in the incidence of specific histologic types of mammary carcinoma among the populations studied. (10 refs)

- 79-2902 Dietary Hypotheses Concerning the Etiology of Human Breast Cancer.** (Eng) MacMahon, B. (Dept. Epidemiology, Harvard Sch. Public Health, 665 Huntington Ave., Boston, MA, 02115). *Nutr and Cancer* 1(2): 38-41; 1979.

Epidemiologic and experimental evidence for an association between diet and human breast cancer (BC) is presented, and some hypotheses on the role of diet in the etiology of BC are presented. The three principal features of the distribution of BC in humans are the striking geographic variation in incidence and mortality, its inverse association with age at first pregnancy, and a cluster of associations pointing to a critical role for ovarian activity in the genesis of the disease. Although there is no direct evidence of an influence of specific dietary factors on BC, some such factor is probably involved, as indicated by the overall geographic correlation between BC risk and food consumption and by the association of risk with body wt. Several studies have found a positive correlation between fat consumption and BC incidence. Mammary carcinogenesis in rats and mice is inhibited by calorie restriction and enhanced by high-fat diets. The mechanism of action of the high-fat diet is not known, but the possibility of alteration of hormonal states through dietary fat is repeatedly stressed. Considerable evidence points to the importance of the childhood years in determining BC risk. It is suggested that specific dietary factors associated with age at menarche may be the same factors that are the early determinants of BC risk. Studies relating BC risk to a particular pattern of estrogen metabolism have found substantial differences between high- and low-risk populations. These hormone patterns are determined in part by diet, and the specific factors should be determined. (25 refs)

- 79-2903 Opening Address.** (Eng) Mogren, H. (AB Marabou, Sundbyberg, Sweden). *Nutr and Cancer* 1(2): 26; 1979.

The opening address to the sixth Marabou (Sweden) international nutrition symposium dealing with the roles of food, diet, and nutrition in the causation and prevention of cancer is presented. These factors appear to be linked to approx 40% of all cancers in men and 60% of all cancers in women. The role of nutrition in cancer is not well understood. Eating patterns may play a major role in determining the risks of developing certain types of cancer, such as cancer of the breast, prostate, colon, and stomach. Many epidemiologists and nutritionists believe that a large proportion of these cancers may be the result of a diet too rich in total calories, saturated fats,

cholesterol, and alcohol. Instead of presenting basic facts and developments in nutrition, newspapers and magazines too often prefer to sound the alarm and to reproduce quasi-scientific curiosities. It is important to make the point that diet, not any single food, is important in good nutrition. (no refs)

- 79-2904 Health Problems of Anaesthetists and Their Families in the West Midlands.** (Eng) Tomlin, P. J. (Univ. Dept. Anaesthetics, Queen Elizabeth Hosp., Birmingham B15 2TH, England). *Br Med J* 1(6166): 779-784; 1979.

The occurrence of congenital anomalies among the children of 314 anesthetists in the West Midlands region (10% of the anesthetists in England and Wales) was studied. The children born to 60 anesthetists during periods when they were not engaged in anesthetic practice served as controls. Thirty percent of the anesthetists had problems related to unexpected infertility or abortion. The abortion rate was 9.8% in the control group, compared with 18.2% in families in which either parent was an anesthetist ($p < 0.05$). Girls with anesthetist parents were born underweight; boys were not similarly affected. Of the children born to anesthetists, 9.3% had congenital abnormalities or developmental problems, compared with 4.3% of the control group. A significantly greater proportion of girls had major clinical disorders. There was an appreciable excess of locomotor disorders compared with the rate in the general population. Three children had apparent neurological problems, two developed tumors (lymphoma, ependymoma), and a third developed leukemia. Breast cancer occurred in 2/76 female anesthetists and in the wife of an anesthetist; the wife, a dentist, regularly gave dental anesthetics. Six of the 238 male anesthetists also developed cancer (1 lung, 1 rectal, 4 skin cancers). (34 refs)

- 79-2905 Breast Cancer among Atomic Bomb Survivors. The Relationship of Prognosis to Pathologic Findings.** (Eng) Tokunaga, M. (Second Dept. Pathology, Sch. Medicine, Kagoshima Univ., Kagoshima, Japan). *Acta Pathol Jpn* 29(2): 197-209; 1979.

The relationship between intensity of exposure to ionizing radiation, pathologic findings, and prognosis was studied among 360 breast cancer patients living in Hiroshima or Nagasaki at the time of the bomb (ATB) or afterward (not in the city: NIC). The patients were classified by exposure dose into four groups: (1) NIC + 0 rads (nonexposed), (2) 1-49 rads, (3) 50+ rads, and (4) exposure dose unknown. The incidence of breast cancer was significantly higher among Group 3 women than among those in Groups 1 and 2. The 5- and 10-yr survival rates were highest in Group 3 and lowest in Group 2. The 5-yr survival rates tended to decrease gradually with age ATB in Groups 1 and 2, but not in Group 3. There were no statistically significant relationships between radiation dose and histologic type or size distribution

of the tumors. In Groups 1 and 2, 5-yr survival rates were considerably higher among patients with tumors < 5 cm in size than among those with tumors ≥ 5 cm; this relationship between tumor size and prognosis was reversed in Group 3. The prognosis was better in Group 3 than in the other groups, regardless of histologic grade of tumor. The cellular reaction in the carcinoma stroma was significantly greater in Group 3 than in the other groups, and prognosis tended to be better in patients showing a marked cellular reaction. The data suggest that radiation may have both a cancer-inducing effect and a role in the cellular immune reaction against cancer tissue. (23 refs)

- 79-2906 Comparative Clinicopathological Study of Breast Cancer among Japanese and American Women.** (Jpn) Sakamoto, G. (Dept. Pathology, Cancer Inst., Japanese Foundation Cancer Res., 1-37-1 Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Sugano, H.; Hartmann, W. H. *Jpn J Cancer Clin* 25(3): 161-170; 1979.

Breast cancer patients who underwent radical mastectomies during 1956-1974 at the Cancer Institute of Health (CIH) in Tokyo, Japan (2,604 women), and during 1956-1976 at the Vanderbilt University Hospital (VUH) in Nashville, Tennessee (755 women), were compared with respect to histologic type of tumor and 10-yr survival rates (patients seen between 1956-1967 only). The incidence of infiltrative and noninfiltrative lobular cancer was higher in the VUH group (21 and 68 patients, respectively) than in the CIH group (7 and 54, respectively). At the time of surgery, the American women were older than the Japanese women: 54.3% were 30-59 yr old vs 83.4% of the Japanese women, and 45.5% were > 60 yr old vs only 15.2% of the Japanese women. The overall 10-yr survival rate was 63.8% for the CIH and 46.9% for the VUH patients. With respect to lymph node metastasis, the critical point in 10-yr survival rates for Japanese women was the involvement of more than three to four axillary lymph nodes, and the critical point for American women was the presence of any lymph node involvement. For American women the 10-yr survival rate was significantly lower for postmenopausal (34.1%) than for premenopausal women (61.3%), but the survival rates for pre- and postmenopausal Japanese women were the same. (12 refs)

- 79-2907 Estimated Risk and Occurrence of Breast Cancer in Asymptomatic and Minimally Symptomatic Patients.** (Eng) Egan, R. L. (Mammography Section, Emory Univ. Clinic, 1365 Clifton Road, N.E., Atlanta, GA, 30322). *Cancer* 43(3): 871-877; 1979.

Mathematical procedures, some unique to this study, were applied to 114 suggested breast cancer risk factors, with as many as 10 subsets, using data obtained from historical physical, and x-ray examinations of 7,252 patients performed at

a clinic from 1963 to 1977. There were 30,904 individual breast examinations. Biopsies of 3,733 breasts revealed 713 primary breast carcinomas (exclusive of lobular carcinoma in situ) and 3,020 benign lesions. One-fifth of the cancers were unrelated to symptoms; 82% were free of axillary lymph node metastasis. There was no sign or symptom that predicted pre-clinical cancer. Interaction of numerous indicators subjected to strong statistical procedures could contribute to establishing the risk of even early breast cancer. The results of hierarchic discriminant analyses demonstrated the feasibility of using simultaneously large numbers of risk factors in a systematic way to pinpoint patients with mammary cancer. Based on usual clinical and x-ray assessment of the women, 12.5% of the noncancer patients required biopsy to demonstrate 70% of the cancers with a cancer to benign rate of 1 to 4. Using the same data with discriminant analyses, 5.6% of the patients would require biopsy, at the rate of 1 cancer to 1.8 benign lesions; 92% of the cancer patients could be placed in 11.9% of the population. A computerized system has been developed for widespread application to provide the clinician with a highly objective and totally consistent assessment of risk for breast cancer in each patient. (5 refs)

- 79-2908 Adolescent Breast Masses in Nigerian Igbo.** (Eng) Onuigbo, W. I. (FRCPath, PMB 1098, Enugu, Nigeria). *Am J Surg* 137(3): 367-368; 1979.

A total of 137 adolescent Nigerian Igbo (128 females and 9 males aged 11-20 yr) with breast masses were identified through surgical biopsy records dating back to 1970. In seven of the nine males, the histologic diagnosis was gynecomastia. Of the other two, one had an onchocerca worm granuloma on a muscle and the other had a neurofibroma. Of the 128 female patients, 101 were diagnosed as having fibroadenoma, 19 dysplasia, 5 sarcoma, and 1 each adenocarcinoma, abscess, and lymph node mass. Alveolar soft part sarcoma is a rare tumor but was encountered in two girls (aged 15 and 18 yr). This series differed from an American series in that the peak age for gynecomastia was later in adolescent Igbo and the peak age for fibroadenoma was later in adolescent Americans. These patterns may have a hormonal basis. (12 refs)

- 79-2909 ABO Blood Groups and Rhesus Factor in Patients with Tumors and Tumorlike Lesions of the Ovaries.** (Rus) Rybalka, A. N. (Dept. Obstetrics and Gynecology, Crimean Medical Inst., Simferopol', USSR); Andreev, P. V.; Tikhonenko, L. F.; Koval'chuk, N. A. *Vopr Onkol* 25(3): 28-30; 1979.

The distribution of blood groups ABO and the Rhesus (Rh) factor was determined in a group of 1,750 women with various tumors and tumorlike lesions of the ovaries. There was a decreased frequency of group O (16.1% vs 32.1% in healthy donors) and an increased frequency of group AB (25.8% vs 8.6%) among patients with mucinous tumors. Among pa-

tients with the cysts of the corpus luteum, there was a decreased frequency of group O (24.1%) and an increased frequency of groups A (45.6% vs 39.6%) and B (22.8% vs 19.7%). Among patients with endometrioid tumors, there was a decreased frequency of group A (32.7%) and an increased frequency of groups O (36.5%) and AB (15.4%). There was a decreased frequency of group B (12.5%) among patients with malignant tumors. The occurrence of the Rh-negative phenotype was significantly decreased among almost all patients with tumors and cysts of the ovaries (3.0%-7.48%), but not among patients with mucinous and malignant ovarian tumors (16.1% and 14.1%, respectively). (9 refs)

- 79-2910 Long-Term Estrogen Use and Endometrial Carcinoma (Letter to Editor).** (Eng) Obrink, A. (Dept. Gynecologic Oncology, Radiumhemmet, S-104 01 Stockholm, Sweden); Collen, J.; Bunne, G.; Tjernberg, B. *Acta Obstet Gynecol Scand* 58(1): 123; 1979.

Analysis of 622 patients with endometrial adenocarcinoma and 1,428 age-matched controls demonstrated a progressive increase in the number of women taking noncontraceptive estrogens for > 6 mo in both groups. Among the patients, the number increased from 8.1% in 1974 to 35.6% in 1977; these values for the controls were 6.6% and 16.7%. Further analysis revealed that between 1976 and 1977, short-term use (< 3 yr) was similar in the controls and patients, but long-term use (3-6 yr) was more than five times as common among the patients. (no refs)

- 79-2911 Assessing the Risks from Menopausal Estrogen Use: What Can We Learn from Trends in Mortality from Uterine Cancer?** (Eng) Weiss, N. S. (Dept. Epidemiology, Sch. Public Health and Community Medicine, Univ. Washington, Seattle, WA, 98195). *J Chronic Dis* 31(12): 705-708; 1978.

Errors in estimating endometrial cancer mortality rates and the application of mortality data to assessing the risks from menopausal estrogen use are surveyed. The best measure of endometrial cancer mortality in the US that is routinely available is the sum of the following two cause-of-death categories, cancer of the corpus uteri and uterine cancer not otherwise specified (NOS). However, the ability to document a trend in endometrial cancer mortality by tabulating deaths in these categories is limited by the fact that cervical cancer deaths, which once constituted a substantial proportion of deaths assigned to uterine cancer NOS, are with time probably contributing less and less to this category. Nevertheless, endometrial cancer mortality probably has had a true decline during the 1950's and 1960's, most likely as a result of increasingly early recognition and treatment of the disease. It is uncertain whether the spurious or the real reasons for declining mortality from corpus cancer + uterine cancer NOS

are continuing into the late 1970's. Thus, it is difficult to correlate time trends in uterine cancer mortality with the increased prevalence of estrogen use. Failure to observe an increase in the apparent mortality rate might only mean that the rise in estrogen-associated deaths was not enough to compensate for the fall that was otherwise taking place. These uncertainties could be clarified by a contemporary review of deaths assigned to uterine cancer NOS to determine their "true" nature and by obtaining data regarding the volume of sales of commonly used estrogen preparations. - 79-2912 Occupation and Prostatic Cancer. A Review and Retrospective Analysis Based on Death Certificates in Two California Counties.** (Eng) Ernster, V. L. (Dept. Epidemiology and International Health, Univ. California, San Francisco, CA, 94143); Selvin, S.; Brown, S. M.; Sacks, S. T.; Winkelstein, W.; Austin, D. F. *J Occup Med* 21(3): 175-183; 1979.

Possible relationships between occupation and prostatic cancer (PC) were examined by comparing the occupations of men who died of PC in two northern California counties, Alameda (368 PC deaths) and San Francisco (334 deaths), with controls matched for sex, age, race, date of death, and county of residence. The data are presented as the mean odds ratio, which is an expression of the risk of being employed in a specific occupation/industry associated with cases compared with controls, and as a comparison of the observed number of PC deaths for each occupation/industry with the expected number. The data were analyzed separately for the two counties. Of 28 occupations that were sufficiently represented for consideration in both counties, elevated odds ratios were found for bookkeepers, shipping and receiving clerks, compositors and typesetters, and shipfitters. Of the 21 industries sufficiently represented in both counties for cross-county comparisons, elevated odds ratios were confirmed for horticultural services; newspaper publishing and printing; motor vehicle dealers; drug stores, drugs, chemicals, and allied products; and miscellaneous personal services. This study tentatively supports the possibility that selected occupations and industries have an excess risk for the development of PC. (23 refs)

- 79-2913 Prostate Cancer Epidemiology: Widowerhood and Cancer in Spouses.** (Eng) Greenwald, P. (Div. Epidemiology, New York State Dept. Health, Tower Building, Empire State Plaza, Albany, NY, 12237); Kirmss, V.; Burnett, W. S. *J Natl Cancer Inst* 62(5): 1131-1136; 1979.

A study was made to determine whether the duration of widowerhood (WHD) among men with prostate cancer differs from that of matched controls. Duration of WHD and the incidence of cancer deaths in spouses were studied in 169 widowers dying with prostate cancer, 451 matched control widowers dying of any causes except prostate cancer, and 150

matched control widowers dying of other types of cancer. The av duration of WHD and frequency of multiple wives were the same for patients with prostate cancer and controls. The incidence of breast cancer in predeceased wives (ie, wives dying before their husbands) of the prostate cancer patients was 9.9%, compared to with 5.8% in predeceased wives of the controls. The respective endometrial cancer rates for predeceased wives of patients and controls were 2.0% and 0.2%. Neither these results nor the results from a confirmatory study of cancer among wives of married prostate cancer patients were statistically significant. Overstatement of WHD status on 6.1% of death certificates, lack of case-control differences in durations of WHD, and decreasing widower-married mortality ratios as age-specific groupings were made smaller indicated that the high rates of prostate cancer among widowers may be due to artifacts of classifying and tabulating vital records. (12 refs)

- 79-2914 Descriptive Epidemiology of Testicular and Prostatic Cancer in Los Angeles.** (Eng) Ross, R. K. (Dept. Community and Family Medicine, Univ. Southern California Sch. Medicine, 2025 Zonal Ave., Los Angeles, CA, 90033); McCurtis, R. W.; Henderson, B. E.; Menck, H. R.; Mack, T. M.; Martin, S. P. *Br J Cancer* 39(3): 284-292; 1979.

Data from the Los Angeles County Cancer Surveillance Program (CSP) for the years 1972-1975 were used to study the descriptive epidemiology of testicular and prostatic cancer. The very high black/white ratio and late age peak of prostatic cancer contrasted sharply with the very low ratio and early age peak of testicular cancer. However, both sites had higher rates among upper occupational and social class groupings. Available descriptive and analytical research suggests that the etiology of prostatic cancer is most probably related to hormonal influences rather than to a horizontally transmitted agent, but the etiology of testicular cancer is most probably related to endogenous or exogenous hormonal influences in utero or in infancy or to in utero exposure to other exogenous agents. (61 refs)

- 79-2915 Epidemiologic Association Between Endemic Nephropathy and Urinary System Tumors in an Endemic Region.** (Eng) Stoyanov, I. S. (Inst. Oncology, Medical Acad., Sofia 1156, Bulgaria); Chernozemsky, I. N.; Nicolov, I. G.; Stoichev, I. I.; Petkova-Bocharova, T. K. *J Chronic Dis* 31(12): 721-724; 1978.

All cases of endemic nephropathy (EN) and/or malignant urinary tract tumors occurring in 27 villages of the Vratza district of Bulgaria between 1965 and 1974 were analyzed. Fifteen villages had a high EN incidence, and 12 (controls) were nonendemic. In the former group, 645 cases of EN and 177 cases of urinary tract tumors were recorded, whereas the corresponding figures in the control villages were 14 and 30, respectively. Of the cancer patients, 44.6% had concurrent

EN. EN was registered first in 62.8%. The highest risk for urinary tract cancer occurred in patients with EN, followed by persons living in endemic villages but unaffected by EN. Patients with EN had an 88-fold higher risk of urinary tract cancer than persons living in control villages. The data suggest that there is a common etiologic factor(s) in EN and urinary tract cancer. (8 refs)

- 79-2916 Cancer Risks Associated with Employment in the Leather and Leather Products Industry.** (Eng) DeCoufle, P. (Environmental Epidemiology Branch, NCI, Bethesda, MD, 20014). *Arch Environ Health* 34(1): 33-37; 1979.

A recent study of relationships between occupation and cancer at Roswell Park Memorial Institute, Buffalo, New York, identified significantly high risks of bladder cancer among men and women with a history of employment in plants manufacturing leather and leather products. Eleven men and four women with bladder cancer had been employed between 1956 and 1965 in these plants, and their relative risks were estimated to be 6 and 4 times those of clerical workers, respectively. Among the men, the relative risk increased with duration of employment and remained elevated after adjustment for smoking habits. Male leatherworkers also had significantly increased risks for cancers of the buccal cavity and pharynx and larynx that could not be explained by differences in smoking habits. Malignant lymphomas were also associated with elevated risks among men and women who had worked in the leather industry. A review of processes and agents found in leather manufacture revealed several steps that involved exposure to potentially carcinogenic materials, including tannin extracts and tannic acid plus azo and other synthetic dyes, that have induced cancer in laboratory animals. There should be further studies of persons employed in the leathermaking and fabrication industries to characterize the nature of exposure-response relationships. (30 refs)

- 79-2917 Primary Liver Cancer and Occupation: Brazoria County, Texas (Meeting Abstract).** (Eng) Divine, B. J. (Univ. Texas Health Science Center, Houston Sch. Public Health, Houston, TX). *Diss Abstr Int [B]* 39(10): 4827; 1979. (no refs)

- 79-2918 Hepatocellular Carcinoma and Hepatitis B Virus Markers in Europe (Letter to Editor).** (Eng) Vargas, V. (Dept. Internal Medicine, Ciudad Sanitaria de la Seguridad Social, Universidad Autonoma, Barcelona, Spain); Pedreira, J. D.; Vilaseca, J.; Ruiz, J.; Esteban, R.; Hernandez, J. M.; Guardia, J.; Bacardi, R. *Lancet* 1(8118): 721-722; 1979.

Hepatitis B virus markers were found to correlate with the

appearance of hepatocellular carcinoma in both cirrhotic and normal livers in an area of Spain where the carrier rate for hepatitis B surface antigen is lower than that in Greece, Asia, or Africa, but higher than that in Britain or the US. (1 ref)

- 79-2919 Important Epidemiological Considerations and Problems in Evaluating Health Effects of Chemicals (Meeting Abstract).** (Eng) Discher, D. P. (Dept. Industrial and Environmental Medicine, San Jose Medical Clinic, 45 South 17th St., San Jose, CA, 94115). *Tex Rep Biol Med* 37: 94; 1978. (no refs)

- 79-2920 Dose-Response Relationship of Neutrons and γ Rays to Leukemia Incidence among Atomic Bomb Survivors in Hiroshima and Nagasaki by Type of Leukemia, 1950-1971.** (Eng) Ishimaru, T. (Radiation Effects Res. Foundation, Hiroshima, Japan); Otake, M.; Ichimaru, M. *Radiat Res* 77(2): 377-394; 1979.

The incidence of leukemia during 1950-1971 in a fixed mortality sample of atomic bomb survivors in Hiroshima and Nagasaki was analyzed as a function of neutron and γ kerma and marrow doses. Two dose-response models were tested for acute leukemia (AL), chronic granulocytic leukemia (CGL), and all types of leukemia, respectively. Each model postulates that leukemia incidence depends upon the sum of separate risks imposed by γ and neutron doses. In Model I, the risk from both types of radiation is assumed to be directly proportional to the respective doses, but Model II assumes that whereas the risk from neutrons is directly proportional to the dose, the risk from γ rays is proportional to dose-squared. The dose response of the two types of leukemia was found to differ by type of radiation. The data suggested that the response of AL was best explained by Model II, but the response of CGL depended almost linearly upon neutron dose alone, because the regression coefficients associated with γ radiation for both Models I and II were not significant. With respect to AL, at least Model II, it appears that both kinds of radiation can induce this type of leukemia. Although both models fit the data for CGL, the induction of CGL appears principally to depend linearly upon neutron dose alone. If AL and CGL are considered together as all types of leukemia, Model II appears to fit the data slightly better than Model I, but neither model is statistically rejected by the data (25 refs)

- 79-2921 Childhood Cancer and Drugs in Pregnancy.** (Eng) Sanders, B. M. (Childhood Cancer Res. Group, Dept. Regius Professor Medicine, Univ. Oxford, Oxford OX1 9QG, England); Draper, G. J. *Br Med J* 1(6165): 717-718; 1979.

A study was carried out on 11,169 matched case-control pairs

of children (aged up to 15 yr) included in the Oxford Survey of Childhood Cancers to determine whether an association exists between cancer in children and drugs given to their mothers during pregnancy. The mothers of children who developed cancer reported about 25% more illness during pregnancy than mothers of healthy control children. The case:control ratio was particularly high for pulmonary tuberculosis and epilepsy, raising the possibility that the drugs (isoniazid and phenytoin) used in the treatment of these illnesses might be carcinogens. However, despite a slight excess of lymphoma in the children of these mothers, the investigation provided no real evidence of a transplacental drug effect in the etiology of childhood cancer. (6 refs)

79-2922 Electrical Wiring Configurations and Childhood Cancer. (Eng) Wertheimer, N. (Dept. Preventive Medicine, Univ. Colorado Medical Center, Box C-245, Denver, CO, 80262); Leeper, E. *Am J Epidemiol* 109(3): 273-284; 1979.

An excess of electrical wiring configurations suggestive of high-current flow was noted in Colorado in 1976-1977 near the homes of children who developed cancer, as compared with the homes of control children. The finding was strongest for children who had spent their entire lives at the same address, and it appeared to be dose-related. It did not seem to be an artifact of neighborhood, street congestion, social class, or family structure. The high-current configuration was associated with an excess of leukemia, lymphoma, and nervous system tumors. The reason for the correlation is uncertain; possible effects of current in the water pipes or of alternating current magnetic fields are suggested. (19 refs)

79-2923 Tumor Incidence in Human Allograft Recipients. (Eng) Penn, I. (Dept. Surgery, Veterans Admin. Hosp., 1055 Clermont St., Denver, CO, 80220). *Transplant Proc* 11(1): 1047-1051; 1979.

The most common types of tumors that arose de novo after transplantation in 693 patients and the management of transplant patients with preexisting renal neoplasms are discussed. Excluding patients with skin and lip cancers (277) and with carcinoma in situ of the uterine cervix (38), lymphomas occurred in 150/461 transplant patients (33% incidence vs a 3%-4% incidence in the general public). The types of cancer seen most frequently in the general public occur mostly in older age groups; their scarcity in transplant patients may be related to the youth of the recipients, whose average age was 40 and who developed their cancers an average of 38 months after transplantation (range, 1-158 months). The predominant type of lymphoma, reticulum cell sarcoma (93/150 lymphomas), was 350 times more common in renal transplant recipients than in the general population. The CNS was involved in an unusually large number of patients (54/130 patients with non-Kaposi's lymphomas). The risk of skin cancer in renal

transplant recipients was seven times greater than in the general public, with the excess consisting mostly of squamous cell carcinomas. A series of 96 patients with preexisting renal and ureteral tumors was studied. Of 37 patients with symptomatic tumors who underwent transplantation within 12 months after completion of treatment for their malignancies, 51% experienced recurrences or metastases. The corresponding figure for the 25 patients who received transplants > 12 months after anticancer treatment was 4%. Therefore, it is recommended that, whenever possible, transplantation be delayed for at least 1 year after completion of therapy. (7 refs)

79-2924 Epidemiology of Hodgkin's Disease. (Hun) Istvan, L. (Haematologiai Osztaly, Markusovszky Korhaz-Rendelőintézet, Szombathely, Hungary); Gicz, S. *Orv Hetil* 120(6): 319-324; 1979.

An epidemiologic analysis of 166 cases of Hodgkin's disease (HD) diagnosed in the county of Vas, Hungary, during 1953-1973, is presented. The patients included 107 men and 59 women. Compared with the occupational pattern of the general population, industrial workers and white-collar workers were slightly overrepresented among the patients. Although the yearly incidence of carcinoma as a whole nearly doubled during the 20-year period, there was no change in that of HD other than cyclic increases at 3- to 4-year intervals. The onset of the first symptoms peaked during the winter months. The incidence was highest in the age groups 15-40 years and 50-65 years. There was no correlation between the incidence of hepatitis and that of HD. A comparison with 20,000 blood donors, 569 patients with gastric carcinoma, 1,070 patients with gastric ulcer, and 114 patients with chronic lymphocytic leukemia (CLL) showed that the frequency of blood group O was significantly lower among the HD patients and that of A and AB was somewhat higher. The blood group distribution was nearly the same as in the CLL patients. The incidence of Rh D factor was lower in the blood donors and the gastric carcinoma patients, and it was similar in the HD and CLL patients. (84 refs)

79-2925 Abnormal Lymphocyte Responses in Residents of a Town with a Cluster of Hodgkin's Disease. (Eng) Plouffe, J. F. (Div. Infectious Diseases, Dept. Medicine, Ohio State Univ. Coll. Medicine, Columbus, OH, 43210); Silva, J.; Schwartz, R. S.; Callen, J. P.; Kane, P.; Murphy, L. A.; Goldstein, I. J.; Fekety, R. *Clin Exp Immunol* 35(2): 163-170; 1979.

The immunological status of residents of a small rural town in which there was a time-space cluster of Hodgkin's disease (7 cases over a 20-year period) was investigated. A large elevator for the storage of navy beans was located in the residential area which was frequently covered with dust from the elevator. The lymphocyte response of 40 healthy town residents,

12 of whom were members of a family with a Hodgkin's disease patient, to commercial phytohemagglutinin (PHA) and to several extracts of navy beans was assayed in vitro. The lymphocytes of these residents showed increased levels of transformation when incubated with navy bean extracts, compared with lymphocytes of nonresident controls. A PHA with the ability to stimulate lymphocytes was isolated from navy beans and characterized. It had a mol wt (upon gel filtration) of 120,000, a subunit mol wt of 30,000, and it contained 7.8% neutral carbohydrate. The purified lectin agglutinated human RBC types A, B, and O. These preliminary results suggest that environmental mitogens may have significant effects on lymphocyte transformation of a chronically exposed population. Other investigations of time-space aggregates of Hodgkin's disease should include a search for environmental substances that may alter the immune system. (30 refs)

- 79-2926 Host Origin of Lymphomas in Organ Transplant Recipients.** (Eng) Penn, I. (Dept. Surgery, Univ. Colorado Medical Center, Denver, CO, 80262). *Transplantation* 27(3): 214; 1979.

Studies of six organ transplant recipients who developed lymphomas demonstrated that all the lymphomas were of host origin. This was determined by HLA typing of tumor cells and donor and host peripheral blood lymphocytes or by examining tumor cells for X chromatin or for the Y chromosome in cases in which the donor and recipient were of different sexes. Necropsy examination revealed no evidence of neoplasia in the donors, and it was unlikely that the lymphomas were present in the recipients before transplantation. (7 refs)

- 79-2927 Spontaneous Abortions in Sibship of Children with Congenital Malformation or Malignant Disease.** (Eng) Spira, A (Unite de Recherches Statistiques, Institut National de la Recherche Medicale, 94800 Villejuif, France); Lazar, P. *Eur J Obstet Gynaecol Reprod Biol* 9(2): 89-95; 1979.

Information about the incidence of spontaneous abortion (SA) in the sibship of 751 children with cancer/leukemia (CL), congenital heart disease (CHD), strawberry nevus (SN), or mental retardation (MR) was obtained. The number of children in the family and the proportion of mothers having had at least one other pregnancy differed significantly among the four groups, being lowest in the CHD and SN groups. The mean rate of SA's was significantly higher in the CHD and SN groups, and the rate of infant mortality due to congenital malformations or chromosomal aberrations was significantly higher in the CHD groups than in the other groups. The groups did not differ with respect to the gynecologic history of the mother, and this variable was not related to the incidence of SA. The SA rate was significantly in-

creased among mothers who had been exposed to ionizing radiation, compared with those who had not, and among mothers who smoked cigarettes. Irradiation or smoking habits in the fathers was not related to SA incidence. Even when maternal exposure to ionizing radiation and smoking was eliminated, the SA rate was significantly higher in the CHD and SN groups compared with the CL and SRC groups. It is hypothesized that the increased incidence of SA among mothers with CHD children might be a manifestation of a correlation between susceptibilities to certain anomalies of the karyotype and some types of congenital malformations. - 79-2928 Benzene Exposure in the Rubber Coating Industry--A Follow-Up.** (Eng) Pagnotto, L. D. (Massachusetts Dept. Labor and Industries, Div. Occupational Hygiene, 39 Boylston St., Boston, MA, 02116); Elkins, H. B.; Brugsch, H. G. *Am Ind Hyg Assoc J* 40(2): 137-146; 1979.

A follow-up study was made of 38 workers in the rubber coating industry who were exposed to benzene concentrations of 5-90 ppm for 1-24 yr. One case of mild benzene poisoning was reported, but the worker recovered rapidly when he was transferred to a job that did not involve benzene exposure. Some of the other workers had blood pictures that were considered slightly abnormal. The Hb of one worker remained low (12.5 g) and exchanged from 1961 to 1977. However, no blood dyscrasias or leukemias were reported in the group since the termination of benzene exposure in 1964. Four workers retired early because of disabilities and three others died; one from lung cancer, another from heart disease, and the third from coronary sclerosis. The remaining workers were alive and free of serious health problems in 1977. In light of the apparently small margin of safety associated with the former American Conference of Governmental Industrial Hygienists (ACGIH) threshold limit value (TLV) of 25 ppm benzene, the recent reduction to the current ACGIH TLV of 10 ppm seems reasonable. (9 refs)

- 79-2929 Oesophageal Cancer Studies in the Caspian Littoral of Iran: Results of a Case-Control Study.** (Eng) Cook-Mozaffari, P. J. (Medical Res. Council External Staff, Dept. Regius Professor Medicine, Univ. Oxford, Oxford, England); Azordegan, F.; Day, N. E.; Ressicaud, A.; Sabai, C.; Aramesh, B. *Br J Cancer* 39(3): 293-309; 1979.

A case-control study was conducted in northern Iran, where very high rates of esophageal cancer (EP) occur among both men and women, to study factors identified in a previous study as potentially causally related to EP. Information was obtained by questionnaire and by interview. Other tumors (lung, stomach, breast, large bowel, larynx, and pharynx) were included to distinguish findings specific for EP from the general characteristics of cancer patients and to verify that expected associations, such as between lung cancer and ciga-

rette smoking, would emerge under the prevailing field conditions. Each patient had two controls matched for village of residence, age, sex, and language group. Reinterviewing was performed to a limited extent to assess the accuracy of replies to questionnaires. The following were found not to be associated with EC: consumption of sheep's milk, yoghurt, wild spinach, and sesame oil; chewing of nass (tobacco and lime mixture), a habit confined to men; carpet-making; consumption of a special foodstuff (crushed pomegranate seeds, pepper, and raisins) during pregnancy; and salting and sun-drying of meat. The use of opium, bread, and tea could not be assessed in the retrospective framework. Strongly associated with EC risk were low socioeconomic status and a low intake of fresh fruits and vegetables. The two factors had an independent effect, and they were more marked for EC than for the other tumors. (13 refs)

- 79-2930 Esophageal Cancer and Alcohol Consumption: Importance of Type of Beverage.** (Eng) Tuyns, A. J. (International Agency Res. Cancer, 150 Cours Albert Thomas, 69372 Lyon Cedex 2, France); Pequignot, G.; Abbaticci, J. S. *Int J Cancer* 23(4): 443-447; 1979.

The role of alcohol consumption in esophageal cancer in Normandy, France, was assessed by a retrospective study of 312 male patients and 869 age-matched controls. The linear relationship between the logarithm of risk and overall daily alcohol consumption was confirmed after adjustment for tobacco. The role of each specific alcoholic beverage was further investigated by computing relative risks for individuals consuming a given beverage and for those drinking other beverages only, within each overall alcohol consumption category. It was concluded: (1) that there is a linear relationship between the logarithm of risk of esophageal cancer and overall daily ethanol consumption, whatever the beverage; (2) that the effect is more marked for strong beverages (ie, liqueurs, brandies) than for lighter beverages; and (3) that there is an additional risk related to apple brandy and cider. One possible reason for the extra risk related to cider and its distillates might be the presence of carcinogens in these beverages. (13 refs)

- 79-2931 Environmental Health Relationships Between Some Selected Physico-Chemical Parameters in Drinking Water and Cancer Morbidity in the Metropolitan Area of Minneapolis--St. Paul (Meeting Abstract).** (Eng) Rodriguez, G. (Univ. Minnesota, Minnesota, MN, 55455). *Diss Abstr Int [B]* 39(9): 4290-4291; 1979. (2 refs)

- 79-2932 Cancer in Universal and Left-sided Ulcerative Colitis: Clinical and Pathologic Features.** (Eng) Greenstein, A. J. (Dept. Surgery, Mount Sinai Medical Center, One Gustave L. Levy Place, New York, NY, 10029);

Sachar, D. B.; Pucillo, A.; Vassiliades, G.; Smith, H.; Kreel, I.; Geller, S. A.; Janowitz, H. D.; Aufses, A. H. *Mt Sinai J Med (NY)* 46(1): 25-32; 1979.

Cancer developed in 30/267 ulcerative colitis patients admitted to one hospital between 1960 and 1976. The clinical records of these 30 patients were examined to elucidate the clinical and pathologic features of the malignancies. There were 26 patients with 29 colorectal cancers (CRC's), and 4 patients with extraintestinal cancers (adenocarcinoma of the bladder, basal cell carcinoma of the skin, Hodgkin's disease of the lymphocyte-depletion type, and diffuse histiocytic lymphoma involving the lymph nodes of the right groin). The CRC's in this series were more often multiple and more proximal in distribution than colon cancers in the noncolitis population. Signs specifically associated with CRC included a palpable abdominal mass, intestinal stricture and obstruction, and late recrudescence of symptoms. Twenty-one of the 26 patients with CRC had universal colitis and 5 had left-sided disease. Compared with a standard population, the observed-to-expected ratio of CRC incidence among all the ulcerative colitis patients was 8, with the ratio being 11 in universal colitis and 3 in left-sided disease. It is important to recognize that after a sufficiently long interval, cancer may develop in left-sided as well as in universal ulcerative colitis. The mortality from CRC was 50% at 18 mo, with 10/13 deaths being due to metastases. There were 10 5-yr survivors. Long-term survival was not limited to patients with subclinical cancers, since 8/9 5-yr survivors studied by barium enema had positive radiologic findings preoperatively. The long-term mortality from colitis-associated cancer did not appear to be worse than that from CRC in the general population. (32 refs)

- 79-2933 Association Between Chloroform Levels in Finished Drinking Water Supplies and Various Site-specific Cancer Mortality Rates.** (Eng) Hogan, M. D. (Biometry Branch, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC, 27709); Chi, P. Y.; Hoel, D. G.; Mitchell, T. J. *J Environ Pathol Toxicol* 2(3): 873-887; 1979.

Statistical and biological problems of the indirect approach to assessment of the impact of environmental agents on public health are illustrated using the potential association between various site-specific cancer mortality rates and chloroform (CF) levels in finished drinking water supplies. Both unweighted and weighted regression procedures were used to determine to what extent (if any) the results might depend on the weighting scheme adopted. CF exposure data were collected in 1975, but the cancer mortality rates with which they were being associated were for 1950-1969. Given the long cancer latent period, the most relevant exposure data would be those from 1925-1959. Even if the available exposure measurements were consistent over long periods of time, the CF readings might still not be representative of the exposure history of the total population at risk. One of the most

significant factors affecting the results of any general linear regression analysis is selection of the explanatory variables. In this study, the issue of cancer latency period was ignored, and data were lacking on certain risk factors, such as cigarette smoking. Within these restrictions, there was some correlation between CF levels in finished drinking water supplies and cancer mortality for specific sites such as the bladder and rectum-intestine. Associations such as these, however, may not be very meaningful and need to be interpreted with great care. (13 refs)

79-2934 Is the Colon Cancer Incidence in Some Eastern Nebraska Counties the Highest in the World? (Meeting Abstract). (Eng) Mahboubi, E. (Eppley Inst Res. in Cancer, Univ. Nebraska Medical Center, Omaha, NE, 68105); Sayed, G.; Shubik, P. *Proc Am Assoc Cancer Res* 20: 226; 1979. (no refs)

(Registre Bourguignon des Cancers Digestifs, 7, boulevard Jeanne-d'Arc, F 21033 Dijon Cedex, France); Legoux, J. L.; Martin, F.; Klepping, C. *Gastroenterol Clin Biol* 3(1): 88; 1979. (no refs)

79-2936 Stomach Cancer Mortality in the North Central States: High Risk Is Not Limited to the Foreign-Born. (Eng) Kriebel, D. (Center Biology Natural Systems, Washington Univ., Box 1126, St. Louis, MO, 63130); Jowett, D. *Nutr and Cancer* 1(2): 8-12; 1979.

Ethnicity, water supply, socioeconomic status, and urbanization were examined as possible stomach cancer factors among all 174 counties of Minnesota, Wisconsin, and upper Michigan. Multiple regression analysis was used. The proportion of residents born in northern Europe best explains the pattern of stomach cancer mortality in these counties. The settling patterns of Finns, and to a lesser extent of Poles, Norwegians, Danes, and Swedes, are strongly associated with county stomach cancer rates. Socioeconomic status and water supply are less significant. Disregarding socioeconomic status and water supply factors, estimated stomach cancer mortality for these populations is still disproportionately high. Other researchers have identified diet as a major risk factor in stomach cancer and as the prime cause of the ethnicity-stomach cancer association. It is suggested that the natives shared the stomach cancer risk, perhaps by adopting the "high-risk" diet of the foreign-born. (22 refs)

79-2937 Incidence of Stomach Cancer in the Cote d'Or Region of France. Results of Two Years of Sys-

tematic Registration of a Well-defined Population. (Fre) Faivre, J. (Registre Bourguignon des Cancers Digestifs, Faculte de Medecine, 7, boulevard Jeanne-d'Arc, 21033 Dijon Cedex, France); Legoux, J. L.; Martin, F.; Cabanne, F.; Klepping, C. *Gastroenterol Clin Biol* 2(12): 967-972; 1978.

Statistics on stomach cancer obtained from a cancer registry in the Cote d'Or region of France (455,727 inhabitants) are presented. During 1976 and 1977, stomach cancer represented 19% of the reported 913 cancers of the gastrointestinal (GI) tract. The crude annual incidence rate was 24.8/100,000 for men and 13.7/100,000 for women. Stomach cancer was the second most prevalent GI tract cancer in men, ranking after cancer of the rectum, and the third most prevalent GI tract cancer in women, ranking after cancer of the colon and rectum. Histological diagnosis, which was possible in 137 of the cases, showed that 69 were adenocarcinomas and 41 were anaplastic carcinomas. Av age at diagnosis was 70.9 yr in men and 72.7 yr in women. Among the 111 men with stomach cancer, 10 had undergone surgery > 20 yr previously for ulcers (9 partial gastrectomies, 1 gastroenteroanastomosis). In the 2-yr period analyzed, there were 148 deaths due to stomach cancer, representing 25% of the GI tract cancer mortality. (19 refs)

79-2938 Gastric Polyps: Clinical Picture and Management (Meeting Abstract). (Eng) Fabry, T. L. (Dept. Medicine, Mount Sinai Hosp., New York, NY); Frankel, A.; Waye, J. D. *Gastroenterology* 76(5, part 2): 1129; 1979. (no refs)

79-2939 Gastric Polyps: Review of the Literature and Analysis of 37 Cases. (Spa) Esteva, E. A. (Servicio de Gastroenterologia, Hospital Nacional "Profesor Alejandro Posadas", Spain); Cosen, J. N. *Acta Gastroenterol Latinoam* 8(4): 249-258; 1978.

The clinical symptoms in 37 patients (18 men and 19 women, median age 65 yr) with gastric polyps were epigastralgia (17 patients, melena (14), anemia (17), emesis (10), asthenia (9), loss of wt (9), jaundice (4), diarrhea (3), ulcer (3), anorexia (3), dysphagia (2), and palpable tumor (2). Solitary polyps were found in 27 cases: 16 were sessile, 2 pedunculated, the others were not characterized. Twenty-one of these 27 tumors were < 2 cm, and 19 were localized in the antrum, 6 in the corpus, and 2 in the subcardiac region. Multiple polyps were found in 10 patients. Biopsy findings were available for 27 patients: chronic gastritis was found in 14, hyperplasia in 5, adenoma in 3, adenocarcinoma in 3, carcinoid tumor in 1, and lipoma in 1. In the 13 patients studied, gastric secretion was increased in 2, normal in 1, and reduced in 2, and achlorhydria was found in 8. (46 refs)

79-2940 Epidemiology of Gastric Cancer. (Eng) Tulinius, H. (Faculty Medicine, Univ. Iceland, P.O. Box 523, Reykjavik, Iceland). *Nutr Cancer* 1(2): 61-69; 1979.

The epidemiology of gastric cancer (GC) in Iceland and in the world is reviewed, and the etiologic hypotheses that have been formulated, particularly those concerned with the effect of diet, are considered. The incidence of GC has fallen over the last several decades both in Iceland and in the world, with few exceptions. The exceptions are mainly areas with very low GC frequency. Mortality from GC has also fallen during this same period. Genetics and immunological makeup appear to play a relatively small role in the etiology of GC. Nitrosamines, which can be produced both within the human body and by food processing, are potent chemical carcinogens and also are site-specific. Some nitrosamines cause adenocarcinoma in the glandular stomach of experimental animals. It is hypothesized that a large proportion of the GC risk is environmental and that this environmental effect is produced through diet. Case-control studies have shown negative associations between GC and vegetables, fruits, and milk; vitamin C is postulated as a protective factor. (33 refs)

- 79-2941 Stomach Cancer in Mali. Epidemiological, Clinical, and Therapeutic Data on 70 Cases.** (Fre) Guindo, A. (Ecole Nationale de Medecine et de Pharmacie du Mali, B.P. 1805, Bamako, Mali); Duflo-Moreau, B.; Dembele, M.; Daou, F.; Duflo, B. *Ann Gastroenterol Hepatol (Paris)* 15(1): 23-26; 1979.

Seventy cases of gastric cancer were detected in the capital city of Bamako, Mali, during an 18-mo period. The patients included 51 men and 19 women all black, aged 25-68 yr (av 49 yr). Most patients were in the lower socioeconomic level. A high-carbohydrate diet based on rice and millet and the consumption of dried smoked and unsmoked fish, homemade peanut butter, and foods with a high potash content were characteristic. Meat, fruit, and vegetable consumption was low. This diet, and especially components such as dried fish, potash, and, possibly, aflatoxin-contaminated peanut butter, are possible etiologic factors. The monotonous diet is likely to cause atrophic gastritis, which may reduce the defense capacity of the gastric mucosa against carcinogens. The 70 cases correspond to an incidence of 22.2/100,000 in men and 8.3/100,000 in women, but the real incidence is probably much higher (44.4-66.6/100,000 in men and 16.6-24.9/100,000 in women) because many cases are treated by quack doctors. (22 refs)

- 79-2942 Introductory Comments.** (Eng) Stare, F. J. (Dept. Nutrition, Harvard Sch. Public Health, Boston, MA). *Nutr and Cancer* 1(2): 37; 1979.

The great differences in the frequency of various types of cancer in different parts of the world indicate that some environmental factor, most likely diet, is responsible. High rates of cancer of the breast, prostate, and colon generally go together, suggesting a common cause (S). Countries with high rates of these cancers generally have low rates of stomach

cancer and vice versa, most likely indicating separate causes. Diet could affect cancer risk in at least three ways: (1) a dietary deficiency could either promote cancer or fail to offer some naturally occurring form of dietary cancer protection; (2) some direct cancer-causing agent, a food additive or a natural or artificial contaminant, could be eaten; and (3) specific excesses, eg, total calories, alcohol, saturated fats, and cholesterol, could be related to cancer. (no refs)

- 79-2943 Diet and Human Carcinogenesis with Special Reference to Colon Cancer.** (Eng) MacLennan, R. (Unit Cancer Epidemiology and Biostatistics, International Agency Res. Cancer, 150 Cours Albert-Thomas, F-69372 Lyon Cedex 2, France). *Nutr and Cancer* 1(2): 42-45; 1979.

Studies of the role of diet in human cancer, especially colon cancer (CC) are reviewed. Brewery workers in Dublin have a two-fold excess for rectal cancer but only a slight excess for CC, but such workers in Copenhagen show no excess in cancer at either site. Certain beverages, such as alcohol or hot tea, may increase the delivery of carcinogens. Specific dietary components may induce activating or inactivating enzymes and thus modify the response to carcinogen exposure. Nitrosamines and other nitroso compounds may be formed in vivo from ingested dietary precursors. Dietary fat and meat consumption are highly correlated with CC. Obesity has been associated with higher cancer risk, but the mechanism is not known. Dietary fiber may exert a protective effect against CC, and retinoids may inhibit the progression of premalignant epithelial lesions. The geographical variation in the incidence of CC suggests that environmental factors, rather than genetic factors, play the primary etiological role. The distribution of cancers within the large intestine also varies with incidence rate. It has been postulated that bile acids are metabolized to carcinogens that act in the colon and rectum. The amount of dietary fat determines the bile acid concentration and bacterial flora composition in the large intestine. These hypotheses are supported by results from studies of populations at high, medium, and low risk for CC. (23 refs)

- 79-2944 Detection, Localization, and Treatment of Occult Bronchogenic Carcinoma in Nickel Workers.** (Eng) Nelems, J. M. (Dept. Surgery, St. Paul's Hosp., Vancouver, B.C., Canada); McEwan, J. D.; Thompson, D. W.; Walker, G. R.; Pearson, F. G. *J Thorac Cardiovasc Surg* 77(4): 522-525; 1979.

A prospective analysis of sputum cytologic abnormalities occurring in 268 asymptomatic men who had been exposed to nickel sulfide in a sinter plant prior to 1963 was carried out during 1973 and 1974. Twelve men, 11 of them smokers and 1 a former smoker, had malignant cells in their sputum. Their chest radiographs were all normal. Two of these men refused further investigations; one presented 3.5 yr later with extensive squamous cell carcinoma of the right lower lobe and the

other presented 5 yr later with an extensive squamous cell tumor involving the right maxillary sinus. All the remaining asymptomatic men were subsequently found to have squamous cell carcinomas of the lung or larynx. One patient was treated with radiation therapy, and nine were treated via pulmonary resection. Two of the 10 patients died, 1 from recurrent carcinoma and 1 from postoperative hemorrhage. The remainder are alive and well an av of 36 mo postoperatively, and their sputum remains negative for malignant cells. All but one tumor showed invasive properties. The incidence of squamous cell tumors in this study was threefold higher than the incidence that would have been expected from subjects exposed only to cigarette smoke. Cancer related to industrial pollutants may behave differently from cancer associated with smoking alone. (14 refs)

79-2945 Lung Cancer Mortality and Residential Proximity to Industry (Meeting Abstract). (Eng)

Gottlieb, M. S. (Tulane Univ., Sch. Medicine, Public Health and Tropical Medicine, New Orleans, LA, 70112); Shear, C. L.; Seale, D. B. *Proc Am Assoc Cancer Res* 20: 197; 1979. (no refs)

79-2946 Trends in Respiratory System Cancer Mortality in Louisiana: Geographic Distributions in 1950-1969 and 1967-1976 Compared. (Eng)

Rothschild, H. (Dept. Medicine, Louisiana State Univ. Medical Center, New Orleans, LA, 70112); Voors, A. W.; Weed, S.; Vial, L. J.; Welsh, R. A.; Johnson, W. D. *Am J Public Health* 69(4): 380-381; 1979.

Parish (county)-specific mortality rates due to respiratory system cancers (RSC) in Louisiana were investigated for the period 1967-1976. The av annual mortality from RSC increased during the study period, compared with the period 1950-1969, and the increase was observed among whites and nonwhites of both sexes. The age-adjusted rate was much higher among males than females, but the rates for females increased more than those for males. Also, the rates for whites increased more than those for nonwhites. Of Louisiana's 64 parishes, the av annual mortality due to RSC was greater than expected in 19 and less than expected in 7. High mortality rates (in the upper quartile) among males were clustered in the southern part of the state, whereas those for females showed an apparently random geographic distribution. The data indicate that the high mortality rates from RSC in Louisiana are probably sufficiently stable over time to provide substantive data for study. (7 refs)

79-2947 Mortality Experience of Workers in a Vinyl Chloride Monomer Production Plant. (Eng)

Buffler, P. A. (Univ. Texas Sch. Public Health, P. O. Box

20186, Houston, TX, 77025); Wood, S.; Eifler, C.; Suarez, L.; Kilian, D. J. *J Occup Med* 21(3): 195-203; 1979.

A mortality follow-up study was conducted of 464 white men employed in a vinyl chloride monomer (VCM) production plant for at least two consecutive mo between 1948 and 1975. Eight of the 28 deaths in this group were due to malignant neoplasms, 4 from lung cancer. No angiosarcomas or other liver tumors were observed. The eight persons who died of cancer were initially exposed to VCM prior to 1963, and the four with lung cancer, prior to 1958. Six of the 28 deaths, including 2/8 cancer deaths, occurred among a subgroup of 165 workers exposed to 1,4-dioxane. The total number of observed cancer deaths was not significantly different than that expected, but a significant excess was noted for malignant neoplasms of the respiratory system. The effects of smoking, duration of exposure to VCM, and level of exposure and the combined effect of duration and level of exposure were analyzed separately. A 5 yr latency requirement was maintained for all analyses except for the smoking analysis. Using a minimum latency period of 5 yr from the date of initial exposure to VCM, the excess of respiratory cancer was moderate but not significant for the 314 employees satisfying this criterion. Both a longer duration and a higher level of exposure during the first 5 yr were associated with a significant excess of respiratory cancer. However when duration and level of exposure were combined, the results were not significant. In spite of the discrepancy in the results of dose-response analyses, the results suggest that a relationship exists between exposure to VCM and respiratory cancer. (27 refs)

79-2948 The Role of Vitamin A and Ascorbic Acid in Relation to Respiratory System Cancers (Meeting Abstract). (Eng)

Lopez-S, A. (Dept. Medicine, Louisiana State Univ. Sch. Medicine, New Orleans, LA); Yates, B.; Johnson, W. D.; Nze, R. *Am J Clin Nutr* 32(4): 954; 1979. (no refs)

79-2949 Cancer Morbidity and Causes of Death among Danish Brewery Workers. (Eng)

Jensen, O. M. (International Agency Res. Cancer, Unit Epidemiology and Biostatistics, 130 cours Albert Thomas, 69008 Lyon, France). *Int J Cancer* 23(4): 454-463; 1979.

Cancer morbidity and mortality were examined in a retrospective cohort study of 14,313 male members of the Danish Brewery Workers' Union (BWU) to determine the health effects of heavy beer drinking, in particular with respect to the etiology of colorectal cancer. Brewery workers are allowed to consume six bottles (2,100 ml) of light pilsener beer (alcohol content 3.7 g/100 ml) on the premises of the brewery per working day. The cohort included 1,063 mineral-water factory workers with no free ration of beer. Cancer morbidity and mortality were compared with those of the general popu-

lation after adjustment for age, sex, area, and time trends. Cancer morbidity during 1943-1972 was increased for cancer of the pharynx [relative risk (RR) = 2.09] esophagus (RR = 2.09), liver (RR = 1.51), and larynx (RR = 1.98). The risk of these tumors was highest among workers who had had a ration of free beer during ≥ 30 yr of employment. An increased risk of lung cancer (RR = 1.16) corresponded with the risk among persons of low socioeconomic class. These tumor sites accounted for a 9% excess of all malignant neoplasms among members of the BWU. No increased risk for cancer of the colon (RR = 1.07) or rectum (RR = 1.02) was observed. In contrast to studies of alcoholics, only deaths from the above-mentioned cancers, liver cirrhosis (RR = 1.77), and motor vehicle accidents (RR = 1.33) were in excess; total mortality was only slightly above expectation (RR = 1.06). It is suggested that the statistical association between beer and colorectal cancer is of a noncausal nature, that the heavy consumption of weak alcoholic beverages may increase the risk of upper respiratory-digestive tract cancers, and that part of the disease pattern associated with alcoholism may be unrelated to alcohol consumption. (44 refs)

79-2950 Induction of Aryl Hydrocarbon Hydroxylase Activity and Pulmonary Carcinoma. (Eng)

Gahmberg, C. G. (Dept. Bacteriology and Immunology, Univ. Helsinki, Helsinki, Finland); Sekki, A.; Kosunen, T. U.; Holsti, L. R.; Makela, O. *Int J Cancer* 23(3): 302-305; 1979.

Aryl hydrocarbon hydroxylase (AHH) activity in lymphoblasts from normal adult Finns, patients with pulmonary carcinomas, and patients with other types of malignancy was studied. High absolute AHH activity was observed in lymphoblasts from 15% of the normal subjects, 39% of the patients with pulmonary carcinoma, and 17% of the patients with other malignancies. Among the patients with pulmonary carcinoma, those with high AHH activity were an av of 5 yr younger than those with low AHH activity; this difference was statistically significant. Among the parents and children of the high-AHH individuals, there was a 50% frequency of high AHH activity. The data suggest that, after induction, high absolute AHH activity is controlled by an autosomal dominant gene (*Ahh*). Its frequency in the Finnish population is estimated to be 8%. These and other data indicate that after induction, increased absolute AHH activity is important in the development of lung cancer. (17 refs)

79-2951 Rising Lung Cancer Mortality among Nonsmokers. (Eng) Enstrom, J. E. (Sch. Public Health, Univ. California, Los Angeles, CA, 90024). *J Natl Cancer Inst* 62(4): 755-760; 1979.

Data on lung cancer mortality trends among nonsmokers and among the total US population were analyzed. Data from two representative surveys of lung cancer deaths in the US as well

as national mortality statistics and other epidemiologic studies show that the lung cancer mortality rate has risen substantially between 1914 and 1968 among persons who never smoked cigarettes. For white men and women, the relative increase for ages 35-84 yr has been about 30- and 7-fold, respectively. Most of the relative increase occurred before 1935 and was probably due to changes in diagnostic criteria. However, increases have continued up to the present for male nonsmokers, who now apparently have an annual age-adjusted lung cancer death rate of about 25/100,000 persons aged 35-84 yr. The rising lung cancer rate among nonsmokers indicates that factors in addition to personal cigarette smoking have had a significant effect on the mortality rate from this disease. In spite of the limited quality of these data, they suggest that a more complete understanding of lung cancer etiology is needed. (29 refs)

79-2952 Heart Disease, Cancer and Vehicle Travel. (Eng) Robinson, A. A. (16 Quayle St., Sandy Bay, Hobart, 7005, Tasmania). *Med Hypotheses* 5(3): 323-328; 1979.

An hypothesis explaining the observed increase in heart disease, lung and breast cancer, and diabetes associated with the increased use of motor vehicles from 1920 to 1975 is proposed. Because of the influence of visual stimulation on the CNS, an imbalance resulting in upsets in metabolic and neural control is caused. This imbalance can in turn cause a variety of ills that may appear completely unrelated to motor vehicle use. (3 refs)

79-2953 Cancer Mortality in Oil Refinery Workers. (Eng) Hanis, N. M. (Dept. Epidemiology and Preventive Medicine, Faculty Medicine, Univ. Western Ontario, London, Canada); Stavaky, K. M.; Fowler, J. L. *J Occup Med* 21(3): 167-174; 1979.

Cancer mortality rates among Imperial Oil Limited employees during 1964-1974 were examined in a cohort study. Compared with nonexposed employees, workers whose jobs exposed them daily to crude petroleum or its products had more than three times the risk of esophageal and stomach cancer and about twice the risk of lung cancer. In the exposed group, the risks of both cancers increased with increasing duration of employment. In the absence of more complete information on the similarity of the exposed and nonexposed employees, these results cannot be ascribed with certainty to a carcinogenic effect of petroleum. However, there was no other clear explanation for the results, and further study is required. When refinery workers were compared with non-refinery workers without consideration of exposure to petroleum in either group, the refinery workers were found to have twice the risk of cancer of the intestines (including rectum) and other digestive organs. No relationship with duration of employment was evident. Although the increased in-

testinal cancer mortality in the refinery workers was not consistent, bias was not an obvious explanation for the observed relationship. Therefore, the presence on a refinery site of a carcinogen other than petroleum cannot be ruled out. (17 refs)

- 79-2954 The Problem of Asbestosis in Spain.** (Eng) Segarra, F. (Instituto Territorial de Barcelona, Servicio Social de Higiene y Seguridad del Trabajo, Barcelona, Spain). *J Occup Med* 21(4): 279-280; 1979.

The occurrence of asbestosis in Spain is discussed. All of the asbestos used in Spain is imported, about 90% of it being chrysotile. About 75% of the industries associated with a risk of asbestosis are located in the Barcelona area; they include fibrocement, textile, insulation, and automobile parts industries. Of 1,003 workers examined (most from 2 fibrocement industries), 247 had asbestosis. There was a definite correlation between the incidence of the disease and the duration of exposure. Pleural lesions were seen in 220 patients, lung involvement in 108. About 50 asbestosis cases were reported in Spain from 1948 through 1974, and nearly 300 have been detected since 1974. The incidence of lung, colon, and rectal cancer and pleural mesothelioma among the exposed workers has also increased in comparison to that of the general population. It is expected that asbestosis and cancer among exposed workers will increase in the future, partly due to the deplorable hygienic conditions in industries associated with a risk of asbestosis. - 79-2955 Smoking and Health: Statistical Data.** (Afr) Coetzee, A. M. (Afdeling Bedryfsgeondheid, Universiteit van Pretoria, Pretoria, S. Africa). *S Afr Med J* 54(11): 425-426; 1978.

Statistical data on cigarette smoking in South Africa in 1977 are presented. Of the population aged > 16 yr, 29.3% were smokers and 11.8% heavy smokers (> 20 cigarettes/day). The lung cancer mortality in the age bracket 20-65 yr was 1,082, which represented an excess of 691 cases. (1 ref)

- 79-2956 The Mortality of Men in the Rhondda Fach, 1950-1970.** (Eng) Cochrane, A. L. (MRC Epidemiology Unit, Cardiff, Wales); Haley, T. J.; Moore, F.; Hole, D. *Br J Ind Med* 36(1): 15-22; 1979.

A more detailed analysis of material from a 20-yr follow-up survey of men in the mining community of Rhondda Fach, Wales, confirms the similarity between the standardized mortality ratios (SMR's) of miners and exminers in radiological categories 0, 1, 2, 3 and A (120.3, 116.5, 119.0, 115.7, and 120.1 respectively) as well as the difference between these SMR's and that of the nonminers (98.7). The specific death

rates showed a raised SMR for bronchitis and other respiratory diseases, excluding pneumoconiosis (PMC), for all categories, including category 0, but little difference between those for category 0 and those for simple PMC. For carcinoma of the lung, the SMR's were equally low for nonminers and for miners and exminers. The SMR for stomach carcinoma was 113.0 for nonminers, 159.5 for men in category 0, 108.2 for men in categories 1-3, and 184.0 for men in categories A-C. The SMR's for stomach carcinoma are unusual, but they give no support to the suggestion that exposure to dust is an etiological factor. There is little or no suggestion of death rates being related to category of PMC except, of course, when PMC is being dealt with as a specific cause of death. The SMR for leukemia was low. A comparison between the survival rates of men aged 55-64 in Leigh, Lancashire, and those in the Rhondda Fach suggests that nonminers in the two areas have similar survival rates, but that survival rates for category 0 and simple PMC are lower in the Rhondda Fach. - 79-2957 Variations in Nasopharyngeal Cancer Incidence among Specific Chinese Communities (Dialect Groups) in Singapore.** (Eng) Shanmugaratnam, K. (Dept. Pathology, Univ. Singapore, Outram Road, Singapore 3, Singapore). *IARC Sci Publ* 20: 191-198; 1978.

A total of 729 cases of nasopharyngeal carcinoma (NPC: 93.6% confirmed histologically) were diagnosed among the Singapore Chinese population during 1968-1972. Variations in NPC incidence among certain Chinese communities or dialect groups in this population were analyzed. Age-standardized incidence rates for the total Chinese population were 18.4/100,000/yr for men and 7.0 for women; the respective rates for the specific Chinese communities were 14.1 and 4.7 for Hokkien, 18.3 and 6.2 for Teochew, 29.1 and 11.0 for Cantonese, 14.2 and 3.3 for Hainanese, 12.6 and 4.8 for Hakka, and 12.2 and 6.0 for the other dialect groups. All of the Chinese communities in Singapore had high risks for NPC; only the Cantonese had a risk significantly higher than that for the rest of the Chinese population. NPC incidence rates for men and women of the other major racial groups in Singapore were 4.7 and 0.6 for Malays and 0.9 and 0.0 for Indians, respectively. Differences in the use and preparation of food items may be relevant to these patterns of cancer incidence. (21 refs)

- 79-2958 Epidemiological Data on Thyroid Cancer.** (Hun) Balazs, G. (I. sz. Sebeszeti Klinika, Debreceni Orvostudományi Egyetem, Debrecen, Hungary); Lukacs, G.; Csaky, G.; Arday, G. *Magy Onkol* 23(1): 63-67; 1979.

Epidemiological data on thyroid carcinoma are presented on the basis of 142 cases diagnosed over a 23-yr-period in Hungary. Of the 142 patients, 134 lived in a flatland endemic

goiter region (Debrecen). The histological diagnosis was available for 104 cases: differentiated carcinoma was found in 74%, undifferentiated carcinoma in 20%, and sarcoma in 6%. By comparison, differentiated carcinoma was diagnosed in 58% of 149 cases in a mountainous endemic goiter region (Innsbruck), undifferentiated carcinoma in 19%, and sarcoma in 23%. In a series of 224 cases in Vienna (nonendemic goiter region), the incidence of differentiated carcinoma, undifferentiated carcinoma, and sarcoma was 57%, 20% and 23%, respectively. Twenty-nine percent of the Debrecen patients were in the age group 0-20 yr, compared with 2% of the Innsbruck cases and 1.2% of the Vienna cases. The high incidence of struma nodosa in the Debrecen endemic goiter region suggests a relationship between this disease and thyroid carcinoma. (13 refs)

79-2959 Screening Program for Radiation-associated Thyroid Carcinoma (Meeting Abstract). (Eng) Shimaoka, K. (Roswell Park Memorial Inst., Buffalo, NY, 14263); Getaz, E. P.; Razack, M. S.; Rao, U.; Norman, M.; Wallace, H. J.; Shedd, D. P. *Proc Am Assoc Cancer Res* 20: 19; 1979. (no refs)

79-2960 Changing Incidence of Thyroid Cancer. (Eng) Weiss, W. (Div. Occupational Medicine, Dept. Medicine, Hahnemann Medical Coll. and Hosp., 6401 New Coll. Building, 230 N. Broad St., Philadelphia, PA, 19102). *J Natl Cancer Inst* 62(5): 1137-1142; 1979.

The incidence of thyroid cancer was examined temporally and geographically by age and sex from data provided by tumor registries in the US and abroad. The temporal trends in Connecticut showed an increase in annual incidence after 1945, with an especially sudden increase in incidence in women. The increase occurred predominantly in older men and younger women. The increase in young women was confirmed by cohort analysis. The rates rose with age in both sexes, but women have recently developed a secondary peak in the fourth decade of life. The same phenomenon was observed in other US data, but not as clearly in data from 10 foreign registries. These observations are consistent with the hypothesis that x-radiation therapy for benign conditions of the head and neck in childhood is a factor in the increased incidence of thyroid cancer in US women, but some other etiologic or modifying factor should be sought to explain the increased incidence in US men. (23 refs)

79-2961 Incidence of Thyroid and Other Tumors Associated with Radiation Therapy Exposure in Childhood (Meeting Abstract). (Eng) Colman, M. (Div. Radiation Oncology, Dept. Radiological Sciences, Univ. California, Irvine, CA, 92717); Kirsch, M.; Creditor, M. *Int J Radiat Oncol Biol Phys* 4(Suppl 2): 163; 1978. (no refs)

79-2962 Risk Factors for Brain Tumors in Children. (Eng) Gold, E. (Dept. Epidemiology, Johns Hopkins Sch. Hygiene and Public Health, 615 N. Wolfe St., Baltimore, MD, 21205); Gordis, L.; Tonascia, J.; Szklo, M. *Am J Epidemiol* 109(3): 309-319; 1979.

A case-control study was conducted in 15 hospitals in the Baltimore, Maryland area to determine possible etiologic factors associated with brain tumors in children. Eighty-four children with brain tumors diagnosed during 1965-1975 were compared with normal children and with children with other malignancies. Parents of these children were interviewed about a variety of possible etiologic factors, including exposure to chemical carcinogens. Children with brain tumors, as well as children with other cancers, had a greater tendency than normal children to have been first births and to have had higher birth weights. More children with brain tumors had a sibling with epilepsy or seizures than did normal children, and several of the mothers of children with brain tumors had themselves had epilepsy or a stroke at a relatively young age. There were no significant differences between the groups with regard to several maternal characteristics, including smoking during pregnancy and prior radiation exposure. However, the interview data indicated that more children with brain tumors and children with other cancers had been exposed to insecticides in the home than had normal children. Fewer children with brain tumors or with other cancers were reported to have had tonsillectomies than normal children. More of the children with brain tumors and those with other malignancies were reported to have been exposed to farm animals and to sick pets. This is one of the first case-control studies of the epidemiology of brain tumors in children, and the results suggest directions for future epidemiologic studies in this relatively uncharted field. 79-2963 Malignant Ethmoidonasal Tumors. Occupational Etiology of Adenocarcinomas in Woodworkers. (Fre) Gerard, A. (No affiliation given). *J Fr Otorhinolaryngol* 28(3): 200-201; 1979.

Sixty-five cases of malignant ethmoidonasal tumor were found in a hospital series. They included 32 adenocarcinomas, 9 epidermoid carcinomas, and 24 miscellaneous tumors. Twenty-seven of the 32 adenocarcinoma patients were woodworkers (cabinet-makers, joiners, carpenters, etc). The pathogenesis of ethmoidonasal adenocarcinomas in woodworkers is not yet clear. Tannins and hydrocarbons, especially benzo(a)pyrene, encountered during the woodworking process are suspected. In another series of 449 ethmoidonasal tumors, 33.18% occurred in woodworkers, and 92.61% of the woodworkers had adenocarcinoma. The findings indicate that ethmoidonasal adenocarcinoma should be recognized as an occupational disease. The length of employment in woodworking should be limited to 15 yr. (no refs)

79-2964 Some Environmental and Bodily Characteristics of Melanoma Patients. A Case-Control

Study. (Eng) Klepp, O. (The Norwegian Radium Hosp., Montebello, Oslo 3, Norway); Magnus, K. *Int J Cancer* 23(4): 482-486; 1979.

Possible risk factors for malignant melanoma were investigated in a case-control study of 78 Norwegian patients with malignant melanoma and 131 controls with malignant lymphoma, testicular cancer, or bone and soft tissue sarcoma. Cases did not differ significantly from controls with respect to smoking habits, participation in outdoor or indoor sports, sauna habits, hair or eye color, leisure or occupational time spent outdoors, sunbathing, use of UV-lamps, or degree of exposure of different body parts to sunlight. A higher percentage (19.2%) of melanoma patients had been to Southern Europe for sunbathing within the previous 5 yr than had controls (9.2%); the difference was of borderline statistical significance. Significantly more melanoma patients than controls reported very low tolerance to sun exposure as contrasted with very high tolerance, and significantly more melanoma patients than controls reported having freckles or freckling easily. Significantly more male melanoma patients reported using sun lotion during solar irradiation than male controls; no difference was seen among females. (10 refs)

79-2965 Offspring of Patients Treated for Cancer in Childhood. (Eng) Li, F. P. (Div. Epidemiology and Biostatistics, Sidney Farber Cancer Inst., 44 Binney St., Boston, MA, 02115); Fine, W.; Jaffe, N.; Holmes, G. E.; Holmes, F. F. *J Natl Cancer Inst* 62(5): 1193-1197; 1979.

The offspring of a series of survivors of childhood cancer were examined for inherited traits associated with development of the parental tumor and for mutagenic effects of preconception exposures to radiotherapy and chemotherapy. Patients with cancer diagnosed between ages 0 and 17 yr were identified from tumor registries of the Sidney Farber Cancer Institute (Boston, MA) and the Kansas University Medical Center (Kansas City, KS). For 146 patients (84 women and 62 men), 293 pregnancies were reported after cessation of treatment for diverse neoplasms. The outcomes of 286 completed pregnancies were as follows: 242 live births (1 set of twins), 1 stillbirth, 25 spontaneous abortions, and 19 therapeutic abortions. Seven live-born infants died during the first 2 yr of life, a frequency in accord with expectation. Two offspring have developed cancer. One girl and her father had bilateral hereditary retinoblastoma. A second girl developed acute myelocytic leukemia; her mother had received radiotherapy during childhood for a brain tumor. Compared with their cousins and with published figures for the general population, the study progeny had no excess of congenital anomalies or other diseases. Chromosome and immunoglobulin studies of a few offspring did not reveal damage from preconception exposure to cancer chemotherapy and radiotherapy. Findings indicated that large collaborative studies are needed to monitor the offspring of childhood cancer survivors for inherited traits associated with the parental tumors and for mutagenic effects of therapy, particularly intense multimodality treatments. 79-2966 Mouthwash and Oral Cancer: Carcinogen or Coincidence? (Eng) Weaver, A. (Dept. Surgery, Wayne State Univ., Detroit, MI); Fleming, S. M.; Smith, D. B. *J Oral Surg* 37(4): 250-253; 1979.

Two hundred patients with squamous cell cancer of the head and neck were compared with patients from a general surgery group on the use of tobacco, alcoholic beverages, and mouthwash. Patients with cancer of the head or neck used significantly greater quantities of tobacco and alcoholic beverages than the control group. Ten of the 11 nonsmoking and non-drinking patients had used mouthwash at least twice daily for > 20 yr. Only two patients diluted the mouthwash, and nine used a brand containing 25% alcohol. Another six patients used alcoholic beverages and/or tobacco only occasionally, but all used mouthwash excessively. Two case histories are presented, both of which implicate mouthwash as a possible etiological agent in persons susceptible to squamous cell cancer. It is suggested that a history of mouthwash use be determined for all patients with premalignant or malignant lesions of the oral cavity to ascertain whether the use of mouthwash is coincidental to the development of oral cancer or is carcinogenic. 79-2967 Risk of Cutaneous Carcinoma in Patients Treated with Oral Methoxsalen Photochemotherapy for Psoriasis. (Eng) Stern, R. S. (Dept. Dermatology, Beth Israel Hosp., Boston, MA, 02215); Thibodeau, L. A.; Kleinerman, R. A.; Parrish, J. A.; Fitzpatrick, T. B. *N Engl J Med* 300(15): 809-813; 1979.

A 2.1-yr prospective study of 1,373 patients given po 8-methoxypsoralen photochemotherapy for psoriasis revealed 30 patients with a total of 48 basal cell and squamous cell carcinomas. The incidence of cutaneous carcinoma was 2.63 (95% confidence limits = 1.91-3.90) times that expected for an age-, sex-, and geographically matched population. Relative risk to patients with a history of ionizing radiation was 3.68 (99% confidence limits, 2.42-8.69). Patients with a previous cutaneous carcinoma had a relative risk of 10.22 (99% confidence limits, 4.78-37.08). A higher than expected proportion of squamous cell carcinomas and an excess of squamous cell carcinomas in areas not exposed to sun were seen. New patients with known histories of ionizing radiation exposure or of skin tumors should be given 8-methoxypsoralen photochemotherapy only if they understand the risks and have disabling psoriasis untreatable by other means. (30 refs)

79-2968 Squamous Cell Skin Cancer in the North-west of England, 1967-69, and Its Relation to Occupation. (Eng) Whitaker, C. J. (Dept. Occupational Health, Univ. Manchester, Stopford Building, Oxford Road, Manchester M13 9PT, England); Lee, W. R.; Downes, J. E. *Br J Ind Med* 36(1): 43-51; 1979.

During 1967-1969, 781 cases of squamous cell carcinoma of

the skin were reported to the Manchester Regional Cancer Registry, Manchester, England. The male:female ratios were significantly different ($p < 0.001$) among the skin cancer sites. The age-specific incidence rates were significantly different ($p < 0.001$) between the sexes for the 5-yr age groups ≥ 55 yr. Full occupational histories were obtained for 598 patients; a further 148 patients gave one main occupation only, and the remaining 35 patients were untraced. The numbers of patients observed in broad occupational groups were compared with the numbers expected using the 1931 and 1951 censuses. For all skin cancer sites combined, male farmers and textile workers had highly significant excesses of 150% and 135%, respectively. The corresponding excesses for women were 30% for textile workers and they varied from 1,140% to 590% for farmers, but only for the farmers were the excesses highly significant. Male metal workers also showed excesses of 38% and 23% that were of borderline significance. The association between occupation and individual skin cancer sites was then considered. For men there were excesses in the arm for chemical workers, paper/printing workers, and fishermen and in the ears for builders, but these excesses were of borderline significance. There was a significant difference ($p < 0.05$) in the proportion of male patients with atopic skin conditions in each cancer site. However, this was not found for the female patients. For both male and female patients, no significant associations were found between the skin site and either eye color, residence in the tropics, or smoking habit. (23 refs)

- 79-2969 Risk Factors of Lip Cancer: A Critical Evaluation Based on Epidemiological Comparisons.** (Eng) Lindqvist, C. (Finnish Cancer Registry, Liisankatu 21 B, 00170 Helsinki 17, Finland). *Am J Public Health* 69(3): 256-260; 1979.

The incidences of cancer of the lip, head and neck skin, and oral cavity in Finland during 1953 through 1973 were investigated. The mean annual number of new cases of lip cancer was 151 for men and 14 for women; the incidences of skin and intraoral cancers were lower, especially for men. The incidences of lip and skin cancers and, to a lesser extent, intraoral cancer decreased during the 1960's. The incidences of all three cancers increased with age, but unlike the other two, lip cancer showed a marked decrease in incidence in the oldest age groups. The risk of contracting lip cancer was higher in rural than urban areas and higher in the northern and eastern parts of the country than in the south. The risk of skin and intraoral cancers was higher in urban than rural areas. The incidence of lip cancer was negatively correlated with those of skin, colon, and prostate cancers and positively correlated with those of lung, laryngeal, and stomach cancers (the latter 2 in men only). The geographic correlation between the incidence of lip cancer in men and median income was negative, whereas that between the incidence of lip cancer in men and the proportion of those employed in agriculture was positive. The data suggest that lip cancer is etiologically related to upper gastrointestinal and respiratory tract

cancers, but not to head and neck skin cancer. The strong positive association between lip and lung cancer suggests that tobacco smoking is a major common risk factor. (27 refs)

- 79-2970 Solar Keratosis, Pterygium, and Squamous Cell Carcinoma of the Conjunctiva in Malawi.** (Eng) Clear, A. S. (Geographical Pathology Unit., Dept. Morbid Anatomy, St. Thomas's Hosp. Medical Sch., London SE1, England); Chirambo, M. C.; Hutt, M. S. *Br J Ophthalmol* 63(2): 102-109; 1979.

When the histological features of 234 conjunctival biopsies from Africans in Malawi were reexamined, 167 lesions were reclassified as solar keratosis, and all but 1 contained an epithelial abnormality. These abnormalities were graded as hyperplasia or mild dysplasia (126 lesions), moderate dysplasia (19), or marked dysplasia or carcinoma in situ (21). Of the remaining 67 lesions, 54 were classified as invasive carcinomas but 13 could not be classified definitely; several of the latter were considered to be microinvasive carcinomas. Nearly all lesions were associated with solar damage to subepithelial connective tissues. The findings suggest that these lesions represent a continuous spectrum of epithelial abnormality from slight acanthosis and hyperkeratosis through mild and moderate dysplasia to severe dysplasia and carcinoma in situ. The present pathological findings, together with previous epidemiological findings, suggest that UV radiation is the major factor in the development of solar keratosis (pterygium) and, in consequence, the high incidence of squamous cell carcinoma of the conjunctiva in the tropics. - 79-2972 Glycoprotein-containing Factor that Mediates Contact Inhibition of Growth.** (Eng) Lipkin, G. (Dept. Dermatology, New York Univ. Sch. Medicine, New York, NY, 10016); Knecht, M. E.; Rosenberg, M. *Ann NY Acad Sci* 312: 382-391; 1978.

A high-mol-wt glycoprotein-containing factor isolated from conditioned medium from a contact-inhibited (C-I) line of hamster melanocytes was studied for its effects on growth inhibition in cultures of malignant cells. The factor was added at 50 $\mu\text{g/ml}$ to subconfluent cultures of non-C-I RPMI 1846 hamster melanoma cells. At confluence, the treated cultures showed contact inhibition and a characteristic morphologic change from disoriented overgrowth of pleomorphic forms to well-oriented monolayers of fibroblastlike cells. Addition of partially purified melanocyte contact-inhibitory factor (MCIF) to subconfluent cultures of both murine (B16 and S91) and human melanomas produced identical morphologic and growth-inhibitory effects. The growth-inhibitory effects extended to a broad spectrum of transformed and benign cells of ectodermal, mesodermal, and endodermal origins. Maintenance of the C-I morphologic features of MCIF-treated melanoma cultures required intact cytoskeletal structures. In RPMI 1846 cells treated with MCIF, cyclic guanosine monophosphate levels decreased while cyclic AMP increased. An identical protein was detected by polyacrylamide gel electrophoresis in media from every C-I cell type examined but not in any of the non-C-I (malignant) cell types studied. The presence of this glycoprotein, therefore, appears to be correlated with the capacity for density-dependent growth regulation. (20 refs)

- 79-2973 Neoplastic Neuroepithelial Differentiation in an Experimental Transplantable Teratoma.** (Eng) Herman, M. M. (Dept. Pathology (Neuropathology), Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Vandenberg, S. R. *30th Ann Symp Cancer Res* 93-109; 1978.

Neuroepithelial differentiation in the mouse teratoma OTT-6050 was characterized by morphological, biochemical, immunological, and in vitro methods. Ependymal, astrocytic, and neuronal differentiation was demonstrated in continuity with primitive neuroepithelial cells, and intracisternal A particles were found in stem cells and in the more differentiated cell types of OTT-6050. Compared with adult mouse brains, the teratomas showed increased cyclic AMP levels and increased activities of enzymes of the serotonergic, adrenergic, and cholinergic systems. Divergent neuroepithelial differentiation analogous to embryonic neurocytogenesis occurred in vitro within mitotically active cell populations as an early

event and proceeded without apparent tissue relationships to other germ layer derivatives. The divergent differentiation was characterized by astrocytes and neuroblasts. Limited neuroepithelial differentiation also occurred in organ cultures after 39 days in vitro. Brain-associated surface antigenic sites were demonstrated on the differentiating neuroepithelial tissues of OTT-6050. The mouse teratoma alkaline phosphatase was distinct from the kidney and placental isoenzymes, and one-dimensional electrophoresis demonstrated numerous qualitative similarities and quantitative differences between the fetal, neonatal, and adult brain nonhistone chromosomal proteins and those of the teratoma. (64 refs)

- 79-2974 Regulation of Differentiated Functions and Malignancy in Neuroblastoma Cells in Culture.** (Eng) Prasad, K. N. (Dept. Radiology, Univ. Colorado Medical Center, Denver, CO, 80262); Sinha, P. K. *30th Ann Symp Cancer Res* 111-141; 1978.

To determine the possible link between the expression of differentiated functions in cultured neuroblastoma cells and malignancy, the regulation of expression of each individual differentiated function was examined separately. Several conclusions were reached. Cyclic AMP (cAMP) appeared to be one of the important factors in the induction and regulation of several differentiated functions in mammalian nerve cells. A low level of cAMP in dividing nerve cells, which resulted from an increase in cAMP phosphodiesterase activity due to a mutation on the regulatory gene of this enzyme, was responsible for the expression of malignancy and abnormal differentiation. Although no one individual differentiated function seemed to be linked with malignancy, when several of the differentiated functions were expressed at max levels, tumorigenicity was abolished. Thus, the expression of malignancy and abnormal differentiation are apparently linked in neuroblastoma cells in culture. An increased level of cAMP-binding proteins provided one of the important intracellular mechanisms for protecting the formed cAMP from enzymatic hydrolysis during differentiation of neuroblastoma cells. Reduction in histone synthesis and in H_1 -histone phosphorylation may be an important biological signal for the dividing neuroblasts to 'turn-off' cell division. The absence of these events might be indicative of malignant changes. (57 refs)

- 79-2975 Studies of Human Prostatic Acid Phosphatase. II. Characterization with the Use of Anti-Human Prostatic Acid Phosphatase Serum and Application to**

Clinical Diagnosis of Prostatic Carcinoma. (Jpn) Sawada, H. (Gifu Coll. Pharmacy, 5-6-1 Mitahora-higashi, Gifu 502, Japan); Sasaki, E.; Asano, S. *Yakugaku Zasshi* 99(1): 83-89; 1979.

Rabbit antiserum monospecific to purified human prostatic acid phosphatase (PAPase) was used to characterize the enzyme and to determine the feasibility of its use in the clinical diagnosis of prostatic carcinoma. The Ouchterlony double-diffusion technique showed that the antiserum reacted with PAPase but not with RBC APase, serum platelets, or homogenates of brain, lung, liver, or kidney. When PAPase was treated with neuraminidase, it did not lose any of its activity and it reacted with the antiserum. PAPase lost 20%-50% of its activity when it was treated with 1 M urea, 0.01% sodium dodecyl sulfate (SDS), 0.25 M 2-mercaptoethanol (2-ME), or 0.2 M guanidine HCl (GH), and it lost all of its activity and did not react with the antiserum when it was treated with 4 M urea, 0.05% SDS, 1 M 2-ME, or 2 M GH. The antiserum protected the enzyme against heat and pH inactivation. When PAPase was coupled with the antiserum, the activity of the enzyme was stabilized at pH 4.6-5.8 at 56 C. PAPase levels were measured in the sera of 9 normal subjects (2 men, 7 women), 3 prostatic carcinoma patients, and 7 prostatic hypertrophy patients. The results were compared with the amount of PAPase activity inhibited by L-tartrate. Values of total PAPase activity and L-tartrate-inhibited activity were high in the sera of the prostatic carcinoma patients compared with values for the prostatic hypertrophy patients and normal subjects. Among the latter, values were similar for men and women. (35 refs)

79-2980 Heme Biosynthesis in Friend Erythroleukemia Cells: Control by Ferrochelatase. (Eng) Rutherford, T. (Nuffield Dept. Clinical Medicine, Radcliffe Infirmary, Oxford OX2 6HE, England); Thompson, G. G.; Moore, M. R. *Proc Natl Acad Sci USA* 76(2): 833-836; 1979.

The activities of the enzymes of heme biosynthesis (except protoporphyrin oxidase) were followed during the induction of Friend erythroleukemia cells in culture. All the enzyme activities increased after induction with dimethyl sulfoxide. The activities of the intermediate enzymes were much higher than those of δ -aminolevulinate synthase [ALS: succinyl-CoA:glycine C-succinyltransferase (decarboxylating)], the initial enzyme, or ferrochelatase (FC: protoheme ferriolase), the final enzyme of the pathway. FC activity was not detectable in the uninduced cells. ALS activity increased during the first 24 hr of induction; porphobilinogen deaminase activity began to increase after 48 hr and FC activity, after 72 hr. However, the induction of heme synthesis followed the same time course as that of FC activity, not that of ALS activity. The cellular growth medium was found to contain traces of protoporphyrin but not of other porphyrins. Thus, FC is shown to be rate-limiting for heme synthesis during early stages of Friend cell induction. A Friend cell variant (Fw), which is not inducible except in the presence of exogenous hemin, was also studied. All the enzymes of heme synthesis except FC were inducible by butyric acid. FC was not inducible by butyric acid or hemin plus butyric acid. These cells also excreted protoporphyrin. The failure to induce FC activity is believed to be the cause of, not a consequence of, the noninducibility of this cell line. (19 refs)

79-2981 The Cell Surface and the Control of Friend-Cell Differentiation. (Eng) Bernstein, A. (Ontario Cancer Inst., Univ. Toronto, Toronto, Ontario M4X 1K9, Canada); Mager, D. L.; MacDonald, M.; Letarte, M.; Loritz, F.; McCutcheon, M.; Miller, R. G.; Mak, T. W. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 249-260; 1978.

Recent experiments suggesting that membrane changes, both early and late, are an integral part of Friend cell differentiation are summarized. Ouabain, a specific inhibitor of Na^+/K^+ ATPase, induces Friend cell differentiation via its binding to this enzyme. Early changes in the transport of a number of compounds that require a functioning Na^+/K^+ ATPase occur during induction by a variety of different Friend cell inducers. The occurrence and magnitude of these early transport changes have a strong predictive value in

terms of the number of differentiated cells observed 5 days later. Growth of Friend cells in medium in which the relative concentrations of Na^+ and K^+ ions have been reversed induces differentiation in a significant proportion of cells. These results suggest that early inhibition of Na^+/K^+ ATPase is a common step in Friend cell differentiation. It decreases the transport of a number of Na^+ -dependent compounds and may affect other cellular processes that are dependent on Na^+/K^+ ATPase. Another important aspect of this model is that this early inhibition in the Na^+/K^+ ATPase activity is an integral part of the cellular changes that lead to later, inducer-independent events in Friend cell differentiation. (28 refs)

- 79-2982 Chromatin Changes and DNA Synthesis in Friend Erythroleukemia and HeLa Cells During Treatment with DMSO and n-Butyrate.** (Eng) Neumann, J. R. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Riggs, M. G.; Hagopian, H. K.; Whitaker, R. G.; Ingram, V. M. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 261-275; 1978.

Chromatin changes and DNA synthesis were studied in Friend erythroleukemia and HeLa cells during treatment of the cells with dimethyl sulfoxide (DMSO) and n-butyrate. The overall pattern of nuclear phosphoproteins was similar in uninduced and in DMSO-stimulated Friend cells. However, there was an overall decrease in protein synthesis and phosphorylation after 50 hr of DMSO treatment. H1 and H2A were the major phosphorylated histone species both in uninduced and induced erythroleukemia cells. H1 and H2A appeared to be the only histones affected by DMSO induction. The pattern of proteins associated with mono- and oligonucleosomes after 2 min of digestion of nuclei with micrococcal nuclease resembled that produced by the much longer digestion of uninduced cells, indicating that the DNA of DMSO-induced Friend cells is much more accessible to nuclease digestion. N-Butyrate induced a striking accumulation of acetylated histones in HeLa and Friend erythroleukemia cells. Histone acetylation was reversible when cells were shifted to control medium. The rate of incorporation of thymidine, presumably into DNA, was strongly inhibited by n-butyrate in HeLa cells. Both effects of n-butyrate were expressed quite early and had a similar time course, suggesting a close link between the two processes (acetylation of histones and inhibition of DNA synthesis). It is concluded that cytosol from n-butyrate-treated cells contains an inhibitor or dilutes factors needed by the nuclei for DNA synthesis. (59 refs)

- 79-2983 Induction of Murine Erythroleukemia Cells to Differentiate: Cell-cycle-related Events in Expression of Erythroid Differentiation.** (Eng) Marks, P. A. (Cancer Center, Columbia Univ. Coll Physicians and Surgeons, New York, NY, 10032); Terada, M.; Fibach, E.; Ga-

zitt, Y.; Nudel, U.; Reuben, R.; Bank, A.; Rifkind, R. A. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 221-233; 1978.

The relationship between cell-cycle events and transition to Hb production was studied in Friend virus murine erythroleukemia cells (MELC). MELC cultured with the inducers dimethylsulfoxide (DMSO), butyric acid, or dimethylacetamide developed prolonged G_1 or a transient block in initiation of DNA synthesis. There was a decrease in the proportion of cells in S phase during the early period of culture with inducing agents. MELC cultured with inducers remained in G_1 for 6.5-8 hr, compared with 4 hr for cells cultured without inducer. There was evidence that structural changes in chromatin occurred in the course of induced MELC differentiation. A decrease in the rate of sedimentation of DNA on alkaline sucrose gradients was seen with DNA preparations from MELC cultured with either of the three inducers. An increased proportion of MELC could be induced to differentiate by UV radiation when suboptimal concentrations of DMSO were present in the media after irradiation. MELC cultured in 28 mM DMSO for 5 days showed up to 25% benzidine-reactive cells. Actinomycin D (1-2 nanograms/ml) induced >90% of MELC to differentiate after 5 days in the culture. Present evidence suggests that different inducing agents may have different primary sites of action. (21 refs)

- 79-2984 Phospholipid Metabolism of 3T3 Mouse Fibroblasts after Serum Stimulation and Through the G_1 and S Cell Cycle Phases: Incorporation and Disappearance of ^{32}P .** (Eng) Dubois, C. (Laboratoire de Biochimie I, Faculte de Medecine Saint-Antoine, 27, Rue Chaligny, 75571 Paris Cedex 12, France); Rampini, C. *Biochimie* 60(11/12): 1307-1313; 1978.

The phospholipid metabolism of 3T3 mouse fibroblasts was studied after serum stimulation of arrested cells. Cells were arrested by incubating them in serum-free medium. The phospholipids were analyzed by studying the incorporation and disappearance of ^{32}P into cellular phospholipids at different time intervals after the addition of serum. For phosphatidylethanolamine (PE) and phosphatidylcholine (PC), there was an early peak of incorporation in the G_1 phase of the cell cycle, 6 hr after serum addition. For phosphatidylinositol (PI), there was an intense initial increase of incorporation that continued through G_1 and S. Study of the disappearance of ^{32}P from the different phospholipids indicated that at the beginning of serum stimulation, an intense breakdown of PI occurred, that continued through G_1 and S. Except at the onset, the breakdown of PI was compensated for exactly by its synthesis. These two phenomena were closely linked. The breakdown-synthesis cycle, triggered by serum addition to arrested cells, may be linked to other membrane phenomena triggered by serum stimulation. Study of ^{32}P disappearance also indicated that synthesis of PE, probably from PC, occurred at the G_1 phase, 4 hr after serum addition and the beginning of the chase experiment. (24 refs)

- 79-2985 Heterotransplantation of Human Transitional Cell Carcinoma in Athymic Mice.** (Eng) Sufrin, G. (Roswell Park Mem. Inst., New York State Dept. Health, Buffalo, NY); McGarry, M. P.; Sandberg, A. A.; Murphy, G. P. *J Urol* 121(2): 159-161; 1979.

The growth of human transitional cell carcinoma in athymic nude mice and their normal heterozygote littermates was studied. Tumors from 20 patients were transplanted sc into 104 athymic mice. Successful takes were observed with 40% of the tumors and in 39% of the mice. No tumors grew in the normal heterozygotes. The stage of tumor, its histologic grade, its multicentricity and tendency to recur, and the subsequent clinical prognosis were not related to the success or failure of graft takes in the nude hosts. The transplanted tumors formed visible masses 24 hr after implantation, but showed critical periods of growth around 12 days and 20-25 days, when there was either an increase in size or regression. Fully developed xenografts appeared as well-encapsulated solid masses with cytologic and histologic appearances in full accordance with those of the primary tumor. There were no metastases. Chromosome analysis of the xenografts from two patients showed a human karyotype with no mouse chromosomes and a modal chromosome number of 48. (19 refs)

- 79-2986 Establishment of a New Human Chondrosarcomatous Cell Line.** (Eng) Uchida, T. (Dept. Pathology, Nihon Univ. Sch. Medicine, 30-1 Ooyaguchi-kamimachi, Itabashi-ku, Tokyo 173, Japan); Matsumoto, K.; Shimoda, T.; Shikata, T. *Acta Pathol Jpn* 29(1): 51-60; 1979.

A human osteosarcoma cell line (HuOS) was established from the tumor cells of a pulmonary metastasis of chondroblastic osteosarcoma in a 15-yr-old boy. The tumor cell line has been maintained in culture for > 19 mo. Injection of HuOS cells (1×10^7 cells im) into the thigh of seven nude mice produced a tumor at the injection site in all the mice after 1 mo. These tumors were chondrosarcomas, and no evidence of osteoid or bone formation was detected. The electron microscopic appearance of the HuOS cells was that of typical cartilaginous tumor cells with a prominent and dilated granular endoplasmic reticulum, a distinct Golgi apparatus, numerous dark and elongated mitochondria, numerous scattered ribosomes, a few lipid droplets, myelinlike bodies, and occasional small bundles of cytoplasmic filaments. The production of a cartilaginous matrix by the HuSO cells was not detected either histologically or electron microscopically. (18 refs)

- 79-2987 Bronchoscopy in the European Hamster (*Cricetus cricetus*).** (Eng) Reznik, G. (Tumor Pathology Branch, Carcinogenesis Testing Program, NCI, NIH, Bethesda, MD, 20014); Resnik-Schuller, H.; Dickhaus, S. *Lab Anim Sci* 29(1): 85-87; 1979.

The chronological development of induced lung cancer was studied in vivo in the European hamster by a modified pediatric bronchoscope that yielded excellent biopsy specimens for microscopy and cytology studies. (6 refs)

- 79-2988 α -Fetoprotein and Albumin Genes of Rats: No Evidence for Amplification-Deletion or Rearrangement in Rat Liver Carcinogenesis.** (Eng) Sala-Trepat, J. M. (Laboratoire d'Enzymologie, Centre National de la Recherche Scientifique, 91190 Gif-sur-Yvette, France); Sargent, T. D.; Sell, S.; Bonner, J. *Proc Natl Acad Sci USA* 76(2): 695-699; 1979.

Full-length radiolabeled albumin and α -fetoprotein (AFP) complementary DNA's (cDNA's) were synthesized from pure albumin and AFP messenger RNA (mRNA) preparations with the use of avian myeloblastosis virus reverse transcriptase (RNA-dependent DNA polymerase). The cDNA's were used to quantitate the number of albumin and AFP genes in different Sprague-Dawley or Buffalo rat tissues by two independent methods, both of which yielded similar results. First, the kinetics of the association of these cDNA's with nuclear DNA from rat liver, rat kidney, and Morris hepatoma 7777 under conditions of vast DNA excess indicated that the albumin and AFP mRNA's are transcribed from "nonrepetitive DNA." Second, saturation hybridization experiments in which a constant amount of rat liver DNA or Morris hepatoma 7777 was hybridized with increasing amounts of cDNA to albumin mRNA showed that there are one to two albumin genes per rat haploid genome. The number of AFP genes obtained in similar titration experiments was approx two to three. This was true whether rat liver DNA or hepatoma 7777 DNA was used in the reassociation experiments. When high-mol-wt DNA preparations from both these tissues were digested with the restriction endonuclease *EcoRI* and the fragments were transferred to a nitrocellulose filter, the albumin and AFP [32 P]cDNA probes hybridized to different sets of DNA fragments. However, each probe gave the same hybridization pattern whether Buffalo rat liver DNA or hepatoma 7777 DNA was utilized. (22 refs)

- 79-2989 Current Problems in the Choice of Animals for Toxicity Testing.** (Eng) Stevenson, D. E. (Shell Development Co., Westhollow Res. Center, P.O. Box 1380, Houston, TX, 77001). *J Toxicol Environ Health* 5(1): 9-15; 1979.

Animal models for toxicity studies are chosen more for reasons such as life-span, ease of handling, and economics than because of a comprehensive process of validation. There is a tendency to seek the answers to nonspecific questions and then to use those answers in situations in which they cannot lead to proper judgments. (5 refs)

79-2992 Regulation of Hematopoietic Differentiation and Proliferation by Colony-stimulating Factors. (Eng) Burgess, A. W. (Cancer Res. Inst., Walter and Eliza Hall Inst. Medical Res., Melbourne, Victoria 3050, Australia); Metcalf, D.; Russell, S. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 339-357; 1978.

Experiments to characterize the different molecular species of granulocyte-macrophage colony-stimulating factor (GM-CSF) present in mouse lung conditioned medium (MLCM) and the microheterogeneity associated with a particular species of GM-CSF are described. MLCM appeared to contain at least two mol wt species of GM-CSF, but most of the activity [ie, that binding to concanavalin A (Con A)-Sephadex] eluted from Sephadex G-100 as a single peak with a mol wt of 29,000. GM-CSF passing through Con A-Sephadex eluted as two peaks from Sephadex G-100, one at the same elution volume as the GM-CSF that specifically eluted from Con A-Sephadex and the other at higher mol wt. Microheterogeneity was present even in highly purified GM-CSF and could be detected by electrophoresis. The amino acid composition obtained after a 24-hr hydrolysis in the presence of p-toluene sulfonic acid indicated that there were twice as many acidic residues as basic ones. The hexosamine content in this initial analysis was only five to six residues per molecule. The level of incorporation of ³H-labeled amino acids was too low and too nonuniform to produce radiolabeled GM-CSF that would be suitable for sequencing studies. However, it appears to be possible to introduce ¹²⁵I into GM-CSF, but with rather low efficiency and with a considerable loss of biological activity. Thin-layer granulated gel bed isoelectric focusing of GM-CSF and ¹²⁵I-labeled GM-CSF gave an isoelectric point close to pH 4.9. CSF's with other cellular specificities were also analyzed with isoelectric focusing, and each appeared to have distinct isoelectric properties. Thus, the charge distribution on different CSF's appears to be sufficiently different to allow the separation of cell-specific CSF's by isoelectric focusing. (42 refs)

79-2993 Contact Reactions Influencing Cell Locomotion of a Mouse Sarcoma in Culture. (Eng) Abercrombie, M. (Strangeways Res. Lab., Worts' Causeway,

Cambridge CB1 4RN, England); Turner, A. A. *Med Biol* 56(6): 299-303; 1978.

Time-lapse cinematography was used to study contact reactions influencing cell locomotion of the mouse transplantable sarcoma S180 in culture. It is apparent from these studies that contact inhibition exists between S180 cells, although this phenomenon has little influence on their mode of spread, which is largely brought about by diffusive movement. The relatively high (though variable) speed and high rate of turning of S180 cells (which, from the viewpoint of diffusive movement, tend to cancel each other) combine with their compact form and poor mutual adhesion to make the style of movement of S180 cells strangely like that of macrophages. S180 cells show a severe deficiency of contact inhibition by normal fibroblasts, which permits them to invade a population of fibroblasts. However, the deficiency is by no means a total absence of contact inhibition. Compared with the spreading of S180 cells from a focus of high density over an area of substratum free of fibroblasts, spreading during invasion is likely to be slowed by obstruction at the fibroblast front and by diminished speed when on the fibroblasts and quickened by contact guidance from oriented fibroblasts. During invasion, the S180 cells may be largely using the collagen substratum between the fibroblasts for their locomotion. (7 refs)

79-2994 Successively Transplanted Canine Transmissible Sarcoma. (Eng) Koike, T. (Dept. Veterinary Surgery, Faculty of Veterinary Medicine, Hokkaido Univ., Kita-18-jo, Nishi-9-chome, Kita-ku, Sapporo 060, Japan); Kudo, T.; Otomo, K.; Sakai, T. *Gann* 70(1): 115-118; 1979.

Observations from the 21st to the 50th transplant generation of an allogeneic tumor cell line derived from a sarcoma of the external genitalia of a female dog are reported. A total of 170 dogs aged 1-8 mo were observed; the time span required to take the tumor line from generation 21 to 50 was 4 yr, 7 mo. An av of 16.3×10^7 viable tumor cells were inoculated at each transfer. A tumor developed within 4-5 days at the inoculation site in 100% of the dogs inoculated. The tumors regressed in 26 animals, in 17 dogs within 5 mo. Metastasis occurred in 22 dogs, in 15 cases involving the liver and sc tissue of the whole body. The histologic features and karyologic characteristics of the tumor cell line were not modified by the serial transfers. (17 refs)

79-2995 Is Breast Cancer a Result of Endocrine Targeting? (How Women Differ from Rats or Mice). (Eng) Warren, S. (Cancer Res. Inst., New England Deaconess Hosp., Boston, MA, 02215); Brown, C. E.; Chute, R. N. *Ann Clin Lab Sci* 9(2): 87-93; 1979.

An attempt was made to identify hormonal changes occurring in both the surgical castrate and its intact female partner

in parabiosed NEDH rats and to determine the incidence of breast carcinoma (BC) in the intact females. The rats were divided into five groups: (1) 4 pairs, females anastomosed to oophorectomized females; (2) 5 pairs, females anastomosed to castrated males; (3) 7 pairs and (4) 6 pairs, same as Groups 1 and 2, respectively, except that a kidney was removed from each partner; (5) 3 pairs, parabiosed intact females (controls). Of the total 22 female partners of castrated rats, 20 developed BC's. Most of the cancers were multiple, numbering up to six. All female partners in Groups 3 and 4 developed BC. None of the Group 5 rats developed BC. In all groups, follicle-stimulating hormone (FSH) and luteinizing hormone (LH) levels exceeded those of their intact partners, whereas prolactin (PL) levels of the intact partners with BC were more than double those of the castrates. Progesterone (PG) and estradiol (ED) values also exceeded those of the castrate partners. However, all the castrates' sera showed some steroid contact, which is assumed to have resulted from adrenal activity and backflow from the higher levels in the intact partners. The sequence of events culminating in BC is thought to be as follows: castration of the male or female parabiont caused removal of estrogen or testosterone with loss of feedback control over the pituitary secretion of LH and FSH. Crossover of these two polypeptides continuously stimulated the intact partner's ovaries to oversecrete PG and ED in variable amounts. This in turn resulted in oversecretion of PL by the intact partner's pituitary. The interplay between the continuing replicative stimulation of breast epithelium by PL, ED, and PG ultimately terminated in BC. An attempt to weight various factors that may be involved in causing human and experimental (rat) BC suggests significant differences of a quantitative nature. (35 refs)

- 79-2996 Inverse Correlation Between Cell-Surface Adhesiveness and Malignancy in Mouse Fibroblastoid Cell Lines.** (Eng) Bumenik, J. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, 166 10 Prague 6, Czechoslovakia); Perlmann, P.; Fenyo, E. M.; Jandlova, T.; Suhajova, E.; Malkovsky, M. *Int J Cancer* 23(3): 392-396; 1979.

The correlation between tumorigenicity and cell-surface adhesiveness was investigated in eight mouse fibroblastoid cell lines. Three methylcholanthrene (MC)-induced fibroblastoid cell lines (MC 11, 13, and 14) showed similar tumorigenicities after sc injection into 3-mo-old syngeneic recipients. A fourth MC-derived line (MC 15) was significantly less tumorigenic than the other three. As determined by the latex particle adherence assay, the cell-surface adhesiveness of lines MC 11, 13, and 14 was 14.6%-16.7%, whereas that of MC 15 was significantly higher (46.1%). Among the MC 11, 13, and 14 lines, 24.6%-38.9% of the cells attached no latex particles, whereas only 4.6% of the MC 15 cells attached no particles. Approx 50% of all cell lines attached 1-25 particles. The same inverse correlation between tumorigenicity and cell-surface adhesiveness was observed in two lines derived from mouse L cell line (A9 and A9HT) and in two lines

derived from the Sendai virus-induced hybridization of A9HT cells with normal diploid mouse lymphocytes. (25 refs)

- 79-2999 Cell Culture for the Study of Epithelial Cells.** (Eng) Green, H. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139). *Natl Cancer Inst Monogr* (48): 259-262; 1978.

A cell culture system that allows the study of interacting systems is described. The system consists of epidermal keratinocytes and lethally irradiated fibroblasts and permits development of the essential elements of a stratified, squamous epithelium. When line XB teratoma keratinocytes are cultured with medium harvested from fibroblast cultures, they may proliferate or undergo terminal differentiation, depending on the culture conditions. Four independent keratinocyte lines were established in culture from tumors resulting from injection of teratoma PS A4 stem cells into nude mice. When inoculated with lethally irradiated 3T3 cells or with medium that had been in contact with a confluent monolayer of 3T3 cells, they formed colonies with high efficiency. When inoculated in the absence of 3T3 cells, the keratinocytes did not form colonies or they failed to grow through more than a few cell divisions. As with other keratinocytes, they were dependent on fibroblasts for proliferation but not for terminal differentiation. It is likely that other epithelial cell types might be cultivable under cell culture conditions with proper fibroblast support. (14 refs)

- 79-3000 Serum Lactate Dehydrogenase Isoenzymes in Early Malignancy.** (Eng) Ananthanarayanan, P. H. (Dept. Biochemistry, Jawaharlal Inst. Postgraduate Medical Education and Res., Pondicherry-605006, India); Ramakrishnan, S. *Indian J Med Res* 68: 459-465; 1978.

The isoenzyme patterns of lactic dehydrogenase (LDH) in sera from normal humans and from patients with nonmetastatic malignant disease, myocardial infarction (MI), and infectious hepatitis (IH) were studied by polyacrylamide gel electrophoresis. The LDH isoenzymes LD₁ and LD₂ were increased in MI and LD₄ and LD₅ were increased in IH. Total serum LDH activity was significantly increased above normal levels in 14 patients with esophageal cancer, 8 with carcinoma of the prostate, 6 with Hodgkin's disease, 3 with multiple myeloma, and 1 patient each with embryonal rhabdomyosarcoma, ovarian cancer, and neuroblastoma. In

all cases of esophageal and prostatic cancer and Hodgkin's disease, LD₁ and LD₂ were increased markedly, whereas only minimal increases in LD₃ and/or LD₄ were observed. LD₁ and LD₂ were decreased in multiple myeloma; LD₁, but not LD₂, was increased in embryonal rhabdomyosarcoma; and LD₁, LD₂, LD₃, and LD₄ were increased in neuroblastoma and ovarian cancer. Additional isoenzyme bands were observed in the sera from patients with embryonal tumors. The results indicate that serum LDH and the LDH isoenzyme pattern may be of value in diagnosing early malignant conditions. (14 refs)

Subject Index

Abdominal Neoplasms

- Sarcoma
 - Case Report, 79-2871

Abnormalities

- Anesthetics
 - Epidemiology, 79-2904
 - Teratogenic Effects, 79-2904
- Benzo(a)pyrene
 - Cytochrome P-450, 79-2541
 - Teratogenic Effect, Mouse, 79-2541
- Progestational Hormones
 - Epidemiology, Review, 79-2432
- 4,4'-Stilbenediol, α,α' -Diethyl-
 - Genital Tract, Male, 79-2654
 - Semen, 79-2654

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-DNA

- Antibody Reactivity, 79-2580
- Guanosine Monophosphate
 - Antibody Reactivity, 79-2580
 - Immunoglobulins, Fab, 79-2580
- Ligands
 - Antibody Reactivity, 79-2580
- Mammary Neoplasms, Experimental
 - Organ Culture, Mouse, 79-2578

Acetamide, *N,N*-Dimethyl-

- Erythroleukemia
 - DNA Replication, 79-2983

Acetamide, *N*-Fluoren-2-yl-

- Acetohydroxamic Acid, *N*-Fluoren-2-yl-
 - Carcinogenic Metabolite, 79-2579
- Ames Test
 - Enzyme Activation, 79-2505
- Aryl Hydrocarbon Hydroxylases
 - Fibroblasts/Hepatocytes, Hamster, 79-2505
- Cells, Cultured
 - Carcinogenic Metabolite, 79-2579
- Cholangioma
 - Choline, 79-2577
- Contraceptives, Oral
 - Co-carcinogenic Effect, Rat, 79-2660
- Cytochrome P-450
 - DNA, Binding, 79-2506
- Epoxide Hydratases
 - Fibroblasts/Hepatocytes, Hamster, 79-2505
 - Liver, Rat, 79-2486
- Fluoren-2-amine
 - Deacetylation Product, 79-2579
- Food Contamination
 - Laboratory Animals, 79-2576
 - Quantitation Method, 79-2576
- Heme
 - Epoxide Hydratases, 79-2486
- Hepatoma
 - Choline, 79-2577
 - Contraceptives, Oral, 79-2660
 - Mestranol, 79-2660
 - Norethisterone, 79-2660
- Liver Neoplasms
 - Hepatectomy, 79-2600
 - Sarcoma, Reticulum Cell, 79-2600
- Mammary Neoplasms, Experimental

Acetamide, *N*-Fluoren-2-yl- (cont'd)

- Organ Culture, Mouse, 79-2578
- Microsomes, Liver
 - Ames Test, 79-2506
 - DNA, Binding, 79-2506
- Peptides
 - Epoxide Hydratases, 79-2486

Acetamide, Thio-

- Saccharomyces cerevisiae*
 - Mitotic Recombination, 79-2510

Acetic Acid, Dichloro-

- Ames Test
 - Mutagenic Activity, 79-2587
- Ethane, Trichloroepoxy
 - Decomposition Products, 79-2586
- Pangamic Acid
 - Mutagenic Component, 79-2587

Acetic Acid, (Ethylenebis(oxyethylenenitrilo))tetra-

- Cell Transformation, Neoplastic
 - Phospholipids, 79-2786
- Phosphatidylcholines
 - Cell Adhesion, 79-2786
- Phosphatidylethanolamines
 - Cell Adhesion, 79-2786

Acetic Acid, Methylnitrosaminomethyl Ester

- Intestinal Neoplasms
 - Histological Study, Rat, 79-2612
- Peritoneal Neoplasms
 - Carcinogenic Activity, Rat, 79-2612
 - Neurilemmoma, 79-2612
- Splenic Neoplasms
 - Angiosarcoma, 79-2612
 - Carcinogenic Activity, Rat, 79-2612
- Testicular Neoplasms
 - Carcinogenic Activity, Rat, 79-2612
 - Mesothelioma, 79-2612

Acetohydroxamic Acid, *N*-Fluoren-2-yl-

- Acetamide, *N*-Fluoren-2-yl-
 - Carcinogenic Metabolite, 79-2579
- Cells, Cultured
 - Carcinogenic Metabolite, 79-2579
- Guanosine Monophosphate
 - Immunoglobulins, Fab, 79-2580
- Mammary Neoplasms, Experimental
 - Organ Culture, Mouse, 79-2578
- Microsomes, Liver
 - Carcinogenic Metabolite, 79-2579

Acetonitrile

- Ethylene, Chloro-
 - Ames Test, 79-2588
- Ethylene, 1,1-Dichloro-
 - Ames Test, 79-2588

ISSUE 6

THE FRANKLIN INSTITUTE PRESS

CARCINOGENESIS ABSTRACTS

A monthly publication sponsored by the
NATIONAL CANCER INSTITUTE

EDITOR

GEORGE P. STUDZINSKI, M.D., Ph.D.
COLLEGE OF MEDICINE AND DENTISTRY
OF NEW JERSEY, NEWARK

ASSOCIATE EDITOR

JUSSI J. SAUKKONEN, M.D.
JEFFERSON MEDICAL COLLEGE
PHILADELPHIA

NCI STAFF CONSULTANTS

ELIZABETH WEISBURGER, Ph.D.
JOAN W. CHASE, M.S.

Literature Selected, Abstracted, and Indexed
by

Information Services Department, Science Information Services Organization

BRUCE H. KLEINSTEIN, Ph.D., J.D., *Assistant Director, Biomedical Projects*

NANCY H. RUTAN, *Production Manager*

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with The Franklin Institute Research Laboratories for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by The Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index, is \$90.00 U.S., Canada and Mexico and \$120.00 foreign. Individual issues will be charged at \$10.00 to subscribers, \$15.00 each to non-subscribers. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)
ATP	adenosine triphosphate	ml	milliliter(s)
approx	approximately	μl	microliter(s)
av	average	mm	millimeter(s)
BCG	bacillus Calmette-Guerin	mo	month(s)
bid	twice daily	mol wt	molecular weight
C	degree(s) centigrade	N	normal concentration
cal	calorie(s)	NAD	nicotinamide adenine dinucleotide
kcal	kilocalorie(s)	NADH	reduced nicotinamide adenine dinucleotide
cc	cubic centimeter(s)	NADP	nicotinamide adenine dinucleotidephosphate

- 79-3001 Biological and Enzymatic Events in Chemical Carcinogenesis.** (Eng) Pitot, H. C. (McArdle Lab. Cancer Res., Dept. Oncology, Medical Sch., Univ. Wisconsin, Madison, WI 53706). *Annu Rev Med* 30: 25-39; 1979.

The biological and enzymatic events in chemical carcinogenesis are reviewed. Two stages, initiation and promotion, were identified in the carcinogenesis of squamous epithelium. Later, two distinct phases were also identified in rodent hepatocarcinogenesis: the appearance of hyperplastic nodules followed by the appearance of hepatocellular carcinomas after phenobarbital promotion. Hepatic adenomas and focal nodular hyperplasia in humans may be analogous to the hyperplastic nodules in the rat. Hyperplastic alveolar nodules and, possibly, mammary ductal hyperplasias appear to be intermediate stages in rodent mammary carcinogenesis, and preneoplastic lesions in the human breast may be analogous to these lesions. Two-stage carcinogenesis also appears to occur in colon, bladder, and pancreatic tumors. It appears that virtually all chemical carcinogens that are not themselves the ultimate forms undergo reactions to ultimate forms with or without a proximate intermediate form. The enzymatic pathways involved are primarily those associated with microsomal enzymes and the cytochrome P-450 system. Present knowledge of molecular biology strongly suggests that the critical site of action of the ultimate forms of chemical carcinogens is DNA. Promotion does not appear to involve any interaction with DNA, and a likely hypothesis is that promoting agents act as gene activators. (87 refs)

- 79-3002 Specific Genetic Loci as Targets of Carcinogens and Tumor Promoters in Mammals.** (Eng) O'Brien, S. J. (Immunology Section, Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD 20014); Rice, M. C. *J Environ Pathol Toxicol* 2(4): 1055-1068; 1979.

The various classes of cellular genes that are associated with neoplasia are reviewed, with emphasis on their candidacy as subchromosomal targets of carcinogens. The methodology of the detection and mode of action of these genes is discussed as they relate to transformation. Although few carcinogen tests at present are aimed at single genes, it is felt that in the future they may and should be, since a strictly defined carcinogen-testing protocol would ultimately be easier to interpret for purposes of assigning human risk. The second part of this report is concerned with the question of inbred vs outbred mice as a model system for human carcinogenesis. Since outbred mice more closely approximate the polymorphic gene pool

of humans, these animals might be a better test population for carcinogens than inbred mice. Inbred mice are more likely to be fixed for genes that aggravate or abrogate carcinogenic action, leading to false results. The question of how inbred the supply-house-maintained populations of outbred mice become after decades of breeding in a controlled laboratory situation is addressed. A preliminary estimate of the nature and extent of genic variability of Swiss-Webster mice, compared with those of wild mouse and human populations, is given. (61 refs)

- 79-3003 The Predictive Value of Rodent Carcinogenicity Tests in the Evaluation of Human Risks.** (Eng) Tomatis, L. (Unit Chemical Carcinogenesis, International Agency for Res. on Cancer, 69372 Lyon Cedex 2, France). *Annu Rev Pharmacol Toxicol* 19: 511-530; 1979.

The use of rodent carcinogenicity tests to evaluate human cancer risks is reviewed. At least 26 chemical or industrial processes have proved or strongly suspected associations with cancer in humans, and data on the chemicals/processes are tabulated. For 5 processes in which the carcinogenic agent is not known, direct correlations between human and experimental animal (EA) data cannot be made; 4 compounds have not been adequately tested for carcinogenicity; for 15 chemicals, however, a correlation can be made between human and experimental data. These 15 compounds have the same target organ in humans as in at least one of the animal species tested. Multiple target organs were found more often in EA's than in humans. The major criticisms of experimental procedures have been that the route of administration does not correspond to the route by which humans are exposed; the doses sometimes greatly exceed the possible level of human exposure; and the experimental model is too sensitive. Results from a recent survey indicate that the sc route is as reliable as any other in predicting the carcinogenicity of a chemical given by other routes. Whenever a chemical was found to cause cancer in humans, it was because the incidence was exaggeratedly high or the type of tumor induced was rare. Thus, evidence of carcinogenicity in humans is obtained in situations that do not differ greatly from experimental situations, in which the sensitivity of the experimental model is maximized. According to revised International Agency for Research on Cancer (IARC) criteria, in the presence of adequate experimental data and in the absence of adequate human data, chemicals for which there is 'sufficient evidence' of carcinogenicity in EA's should be regarded for practical purposes as if they were carcinogenic in humans. Chemicals evaluated in IARC monographs 1-17 for which there is sufficient evidence of carcinogenicity in EA's are listed. (65 refs)

- 79-3004 A Critical Review: Will the Ames Salmonella Assay System be Used as A Screen for Presumptive Carcinogens?** (Eng) Jacobs, M. (American Inst. Physics, 335 East 45th St., New York, NY 10017). *J Environ Pathol Toxicol* 2(4): 1205-1217; 1979.

The use of the Ames *Salmonella typhimurium* assay as a screen for presumptive carcinogens is reviewed. It should be possible to reduce the incidence of human cancer appreciably by determining which substances in the environment are carcinogenic and then controlling their emission. The Ames test provides a quick, cheap technique by which manufacturers can identify at an early stage chemicals likely to be hazardous. Although the mutation origin of cancers remains an unproved hypothesis, mutagenesis in the Ames assay correlates well with the capacity to induce cancers in laboratory animals. A mutagenic activity ratio >2.5 indicates that the substance has a 95% probability of causing tumors in laboratory animals, whereas an activity ratio of <2.0 indicates that the substance has an 83% probability of being nontumorigenic in laboratory animals. After identifying presumptive carcinogens by the Ames test, one could then analyze human urine for their presence. Analyses of this type might identify individuals who do or do not metabolize carcinogens to the active compounds. The ultimate question is how the regulatory agencies are going to handle the Ames test. There is a growing consensus that a battery of short-term tests is needed and that multiple positive or negative tests would be necessary to define a chemical as a potential hazard or as non-mutagenic. Thus, to what extent the Ames test will be used as a basis for regulatory action is still uncertain. (11 refs)

- 79-3005 Statistical Issues in Interpretation of Chronic Bioassay Tests for Carcinogenicity.** (Eng) Gart, J. J. (Mathematical Statistics and Applied Mathematics Section, Biometry Branch, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014); Chu, K. C.; Tarone, R. E. *J Natl Cancer Inst* 62(4): 957-974; 1979.

The interpretation of chronic bioassay tests for carcinogenicity requires that the data be appropriately recorded. A "case history" for each animal links the pathology data for each organ of each animal to the length of its life. This information can be used in the interpretation of tumor incidences in light of the survival information. The role of historical controls was surveyed, and the use of significance tests in a multidisciplinary approach to the assessment of the pattern of tumor response was suggested. Multiple comparison methods valid for the interpretation of continuous (or measurement) data do not apply to the discrete data analyses used in these studies. The ideas and methods of these studies were applied to an animal study of chloroform. (31 refs)

- 79-3006 Cholesterol and Colon Cancer (Letter to Editor).** (Eng) Oliver, M. F. (Dept. Cardiology, Royal Infirmary, Edinburgh EH3 9YW, Scotland). *Lancet* 1(8122): 931-932; 1979.

The possibility that agents used to treat hypercholesterolemia may be related to the development of colorectal or other visceral cancers is discussed briefly. This possibility has been suggested by the results of small-scale studies in which patients with hypercholesterolemia were treated with clofibrate or with a polyunsaturated fat diet. (7 refs)

- 79-3007 What You Should Know about Estrogens or the Perils of Pauline.** (Eng) Landau, R. L. (Dept. Medicine, Univ. Chicago, 950 E. 59th St., Chicago, IL 60637). *JAMA* 241(1): 47-51; 1979.

The importance of weighing the benefits and risks of estrogen compounds for estrogen replacement therapy is pointed out. Although carefully executed retrospective studies have indicated that the sharply rising incidence of endometrial cancer is linked to the increased use of estrogens in postmenopausal women, it appears that the estrogen dose must be large, continuous, and administered over a long period of time. Smaller doses and cyclic administration apparently reduce cancer risk substantially. (20 refs)

- 79-3008 N-Nitroso Alkylating Agents: Formation and Persistence of Alkyl Derivatives in Mammalian Nucleic Acids as Contributing Factors in Carcinogenesis.** (Eng) Singer, B. (Virus Lab., Univ. California, Wendell M. Stanley Hall, Berkeley, CA 94720). *J Natl Cancer Inst* 62(6): 1329-1339; 1979.

The possibility that differences in the carcinogenicity of alkylating agents are due to differences in their chemical reactions with nucleic acids is discussed. Ethylnitrosourea reacts primarily with oxygens on RNA or DNA, whereas diethyl sulfate reacts almost exclusively with nitrogens. The oxygens are equally reactive in single- and double-stranded nucleic acids, and a good correlation appears to exist between oxygen affinity and the reported carcinogenicity of alkylating agents. When cells or animals were treated with a variety of alkylating agents, persistence of O⁶-alkyl guanine correlated with tumorigenic potential or UV repair deficiency. The available data suggest that the extent of reaction sites of DNA depends only on the alkylating agent used. Although a variety of metabolically activated carcinogens are ultimate alkylating agents, their sites of reaction in vivo generally differ from those of simple, direct-acting alkylating agents. The interaction of ultimate carcinogens with nucleic acids appears to be complex, and mutagenic reactions may play an important role if DNA

REVIEW

modification is the initiating step in carcinogenesis. Experiments on mutations resulting from alkylation of nucleosides indicated that no predictions of base pairing can be made on the basis of chemical structure. It is likely that a given specific group of cells becomes malignant as a result of multiple events, most of which also occur in cells that do not become transformed. With respect to the persistence of specific alkyl derivatives formed in vivo, the removal of any alkyl base is not first order but is at least biphasic. Of the O-alkyl products, only the alkyl phosphotriesters are apparently completely stable in vivo. The alkyl bases are undoubtedly removed in vivo at a rate considerably exceeding that in vitro. (91 refs)

- 79-3009 Some Biochemical Aspects of N-Nitroso Compounds. (Eng) Digenis, G. A. (Div. Medicinal Chemistry, Coll. Pharmacy, Univ. Kentucky, Lexington, KY 40506); Issidorides, C. H. *Bioorg Chem* 8(1): 97-137; 1979.

The occurrence, carcinogenicity, chemistry, formation, inhibition, chemical reactivity, determination, and metabolism of the N-nitroso compounds are reviewed. Most chemical carcinogens produced alkylating or arylating species. The main site of base alkylation in nucleic acids by nitroso compounds is the N-7 position of guanine, but there is no correlation between alkylation at this position and carcinogenicity or mutagenicity. A much better correlation exists with alkylation at the O-6 position of guanine. Of all the chemical carcinogens, only the nitrosamides and some alkylating agents are chemically reactive and do not require enzymic activation to exert their toxic effects. The nitrosamines persist in the body unchanged for much longer periods and require metabolic activation. Thus, the nitrosamines produce cancer only in organs that are capable of metabolizing them. The simplest and some of the higher dialkylnitrosamines are metabolized predominantly in the liver and are activated by α -hydroxylation. The higher dialkylnitrosamines can also be activated by other pathways. It is possible that sulfate or phosphate conjugates of β -hydroxyalkylnitrosamines could serve as direct-acting in vivo alkylating agents. The diversity of the metabolic activation of the higher dialkylnitrosamines is further evidenced by the occurrence of ω - and (ω -1)-hydroxylations. The multiple carcinogenic effects on different organs may be due to the varied metabolic activation of the nitrosamines. There is also evidence that metabolic pathways other than those leading to the formation of alkylating intermediates may exist for N-nitroso compounds. (174 refs)

- 79-3010 Nitrosamines in Cosmetics. (Eng) Anderson, G. A. (Dow Chemical Co., Midland, MI). *Cosmetics Toiletries* 94(5): 65-68; 1979.

The problem of nitrosodiethanolamine (NDEA) contamination in cosmetics is discussed. Analysis of production grade samples of triethanolamine for NDEA contamination gave negative results. Possible sources of nitrite contamination, ie, the drums, cosmetic ingredients, water, and air, are being investigated. (22 refs)

- 79-3011 Food. (Eng) Yeransian, J. A. (General Foods Technical Center, White Plains, NY 10625); Sloman, K. G.; Foltz, A. K. *Anal Chem* 51(5): 105R-134R; 1979.

An extensive literature review concerning advances made in the analysis of foods between 1976 and 1978 is presented. Specific topics include additives; adulteration, contamination, and decomposition; carbohydrates; color; enzymes; fats, oils, and fatty acids; flavors and volatile compounds; organic acids; nitrogen; and vitamins. (1,147 refs)

- 79-3012 Identifying Environmental Chemicals Causing Mutations and Cancer. (Eng) Ames, B. N. (Dept. Biochemistry, Univ. California, Berkeley, CA 94720). *Science* 204(4393): 587-593; 1979.

The identification of environmental chemicals that cause mutations and cancer is reviewed. Damage to DNA appears to be the major cause of most cancers and genetic birth defects, and it may contribute to aging and heart disease. Many of these agents are natural chemicals present in the human diet as complex mixtures. Because of the time, expense, and difficulty of dealing with complex mixtures, existing animal tests and human epidemiology studies are inadequate for identifying the environmental chemicals that cause this damage. Over 50,000 chemicals are currently used in significant quantities, and approx 1,000 new chemicals are introduced each year. The *Salmonella* assay and other short-term assays that have been developed for determining the mutagenicity of chemicals or their ability to interact with DNA should prove useful in detecting chemical mutagens. A very high percentage of carcinogens tested in the *Salmonella* assay are mutagens, and most mutagens appear to be carcinogens. Among the mutagens subsequently found to be carcinogens are furylfuramide, ethylene dichloride, ethylene dibromide, tris(2,3-dibromopropyl)phosphate, and oxidative-type hair dyes. Much of the cancer occurring today appears likely to be due to the ingestion of natural carcinogens in the diet. Since each short-term test detects a few carcinogens that the others do not, a battery of short-term tests is now favored by many investigators. A knowledge of carcinogenic potency would be an important aid in assessing human risk. The short-term tests could be used to establish priorities among the many mutagens that have never been tested in animal cancer models and to which there is significant human exposure. (57 refs)

- 79-3013 Deadly Legacy: Dioxin and the Vietnam Veteran.** (Eng) Thomasson, W. A. *Bull At Sci* 35(5): 15-19; 1979.

Dioxin, a contaminant of a herbicide [(2,4,5-trichlorophenoxy)acetic acid] widely used in Vietnam, apparently caused numbness and tingling in the hands and feet, depression, irritability, memory loss, and even cancer in veterans 8-12 yr after their last exposure. Some had fathered deformed children. Extremely small amounts of dioxin caused death in mice and rats, and rats fed a diet with as little as 5 parts per trillion dioxin developed tumors. The chemical also produced mutations in *Salmonella* and other bacteria. (13 refs)

- 79-3014 Lung Cancer due to Chemicals.** (Eng) Weiss, W. (Hahnemann Medical Coll. and Hosp., Philadelphia, PA). *Compr Ther* 5(2): 18-23; 1979.

Lung cancer due to exposure to coke oven fumes, arsenic, nickel, chromate, chloromethyl ethers, gas, and mustard gas is reviewed. In a study of coke oven workers, the relative risk of lung cancer was 6.9 for men with ≥ 5 yr of employment on top of ovens, 2.1 for men with ≥ 5 at the side of ovens, and 1.7 for men with < 5 yr exposure. In a group of 173 exposed and 1,809 unexposed arsenical workers, the relative risk was dose-related and elevated, reaching 7.0 for those exposed for > 8 yr to compounds containing an equivalent level of $1 \text{ mg/m}^3 \text{ As}$. In a study of smelter workers, there was an inverse relationship between carcinogenic dose of As and induction period. Studies of men exposed > 5 yr to Ni indicate that the elevated risk of nasal and lung cancer is limited to workers exposed prior to 1925. The form of Ni that is carcinogenic in humans is not known. Some studies of chromate carcinogenicity in the respiratory tract have shown very high relative risks. There are no adequate data for a dose-response relationship. The relative risk from exposure to bis(chloromethyl) ether and/or or chloromethyl methyl ether was 29.1 over a 10-yr observation period, and there was a strong dose-response relationship: for 20 chemical workers with heavy cumulative exposure, the relative risk was 77.4. There was an inverse relationship between cigarette smoking and lung cancer incidence in workers exposed to chloromethyl ethers. The relative risk of lung cancer following exposure to mustard gas was 36.7. The occurrence of bronchogenic carcinoma at a relatively early age (< 55 yr) should raise suspicion of exposure to a potent environmental carcinogen. (15 refs)

- 79-3015 Cancer Incidence (Letter to Editor).** (Eng) Wilson, R. (Energy and Environmental Policy Center, Harvard Univ., Cambridge, MA 02138). *Science* 203(4387): 1293; 1979.

If there is a proportional relationship between cancer incidence and dose, then exposure of more people to fixed dose will produce either the same total number of cancers spread over more persons (if there is no threshold dose) or fewer total cancers (if there is a threshold dose). This argument is applied to the current popularity of self-service gas stations and the exposure of customers to the gasoline additive ethylene dibromide. (no refs)

- 79-3016 Dose Comparisons in the Effects of Radiation and of Chemical Pollutants.** (Eng) Glubrecht, H. (Institut für Biophysik der Universität Hannover, Hannover, W. Germany). *Atomkernenergie Kerntechnik Bd* 33(2): 126-129; 1979.

Present knowledge of the effects of chemical pollutants (particularly carcinogenesis, mutagenesis, and teratogenesis) is far behind knowledge concerning the effects of ionizing radiation. If the action of a chemical pollutant can be represented by a dose-response curve, the rad-equivalent of a given dose of the chemical can be expressed by the product of concentration and time. (no refs)

- 79-3017 Materials for Human Implantation.** (Eng) Rostoker, W. (Univ. Illinois, Chicago Circle, Chicago, IL 60680); Galante, J. O. *Trans Am Soc Mech Eng* 101(1): 2-14; 1979.

The characteristics of materials used in devices to maintain or restore body functions are reviewed. A long-term complication of the use of artificial materials in the human body is tumor development. Rodent studies show that the chemical reactivity, physical characteristics, geometry, and surface texture of the material may be important in this type of carcinogenesis. Differences in the carcinogenicity of various substances may be related to whether or not the implant can be entirely encapsulated in a fibrous sheath. Available data indicate that polyethylene particles shed from polyethylene prostheses in clinical use are not carcinogenic in humans or animals. (103 refs)

- 79-3018 Radiotherapeutic Agents: Properties, Dosimetry, and Radiobiologic Considerations.** (Eng) Saenger, E. L. (Radioisotope Lab., Cincinnati General Hosp., Cincinnati, OH 45267); Kereiakes, J. G.; Sodd, V. J.; David, R. *Semin Nucl Med* 9(2): 72-84; 1979.

The properties, dosimetry, and radiobiologic characteristics of radiotherapeutic agents are discussed. Various factors have tended to decrease interest in radionuclides for therapy in recent years. The radiation dose to target tissue depends on biologic (the time concentration

REVIEW

of radioactivity within the target) and physical (the type and energy of the ionizing radiation in the radioactive decay) parameters. A formula for calculating radiation dose estimates to total body and specific organs for administered radionuclides is given. Radiobiologic considerations include the possibility of early deleterious effects from overdosage and chromosomal changes in circulating lymphocytes. Carcinogenesis, a possible late effect, has been minimal in patients receiving therapeutic levels of radioactive drugs. Genetic and developmental effects have also been negligible. Complications encountered more frequently have been leukemia after extensive therapy of thyroid carcinomas, and local fibrosis has developed after direct injection of radioactive colloids into tumor tissue. (55 refs)

79-3019 NAS Study on Radiation Takes the Middle Road. (Eng) Marshall, E. (No affiliation given). *Science* 204(4394): 711-714; 1979.

Most members of the committee on the Biological Effects of Ionizing Radiation have concluded that injury from and exposure to radiation decrease at the same rate. Six members, however, filed a dissenting opinion, claiming that the majority report was alarmist. This group believes that as exposure decreases, injuries taper off more rapidly. They also claim to have found errors in some of the data supporting the majority conclusion. (no refs)

79-3020 Biological Effects of ^{125}I . (Rus) Kalistratova, V. S.; Tishchenko, G. S. *Med Radiol (Mosk)* 24(4): 69-72; 1979.

Available literature on the biological effects of ^{125}I are reviewed, and the data are compared with those for ^{131}I . Administration of 200, 140, and 92 μCi ^{131}I to mice resulted in atrophy of the thyroid, whereas administration of 400 μCi ^{125}I did not. (25 refs)

79-3021 Purification and Assay of Murine Leukemia Viruses. (Eng) Sherr, C. J. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD 20014); Todaro, G. J. *Methods Enzymol* 48: 412-424; 1979.

Techniques for growing murine leukemia viruses (MuLV) in tissue culture, methods for purifying virus in sufficient quantities for biochemical studies, and quantitative in vitro assays for viral replication are described. Among the latter is the supernatant reverse transcriptase assay, which depends on the packaging of RNA-dependent DNA polymerase activity in extracellular C-type viral particles. A linear correlation generally exists between the amount of reverse transcriptase activity and the number of infectious

particles. The most useful viral structural proteins for radioimmunoassays (RIA) are p30 and gp70; a representative RIA protocol for MuLV p30 is described. In the mixed culture cytopathogenicity test, XC cells infected with MuLV's undergo syncytium formation resulting in the appearance of plaques. The number of plaques is a direct function of the number of infectious viral particles. The Moloney sarcoma-positive, leukemia-negative strain of mouse sarcoma virus can transform susceptible cells from a variety of mammalian species. In the secondary focus-formation test, several nonproducer lines show plaque formation when infected by MuLV's, and the number of plaques is directly proportional to the infectious virus concentration. (34 refs)

79-3022 Latent Infection Caused by Herpesvirus. (Rus) Raichani, I. (Inst. Virology, Bratislava, Czechoslovakia); Santo, I. *Vopr Virusol* (2): 99-105; 1979.

Current data on the structure and replication of herpes simplex virus during nonproductive interaction with the host cell are reviewed. It is suggested that latent infection without virus release can undergo transition into persistent infection and vice versa. (72 refs)

79-3023 The Structure and Isomerization of Herpes Simplex Virus Genomes. (Eng) Roizman, B. (Marjorie B. Kovler Viral Oncology Lab., Univ. Chicago, Chicago, IL 60637). *Cell* 16(3): 481-494; 1979.

The structural properties of herpes simplex virus (HSV) DNA's are discussed. HSV-1 and HSV-2 DNA's are linear double-stranded molecules approx 100×10^6 in mol wt, and they have a base composition of 67 and 69 G + C mole %, respectively. The DNA's are fragmented upon denaturation with alkali. The sequence arrangement of HSV DNA consists of two covalently linked long and short components (designated L and S) that comprise 82% and 18% of the viral DNA, respectively. Each component consists of largely unique sequences bracketed by inverted repeats. The L and S components can invert relative to each other, so that DNA extracted from wild-type virions consists of four equimolar populations differing from each other solely in the orientation of the L and S components. The origin of the inversions is discussed in detail. Apparently, the four isomers of HSV-1 DNA are not functionally equivalent, although there is evidence that the terminal portions of the reiterated sequences in the L and S components are obligatorily identical. It is possible that HSV DNA has two sites for the initiation of DNA synthesis, one in the S and one in the L component. The DNA appears to be replicated by a rolling circle mechanism. A model of DNA replication is presented, and predictions based on it are evaluated. The hypothesis that HSV originates by the fusion of two genomes, each bracketed by its own inverted repeats, seems plausible. (59 refs)

- 79-3024 Burkitt's Lymphoma and Infectious Mononucleosis.** (Eng) Wright, D. H. (Univ. Southampton Medical Sch., Southampton SO9 4XY, England). *Compr Immunol* 4: pp. 391-424; 1978.

Evidence linking Epstein-Barr virus (EBV) with infectious mononucleosis (IM) and Burkitt's lymphoma (BL) is reviewed. The anatomical distribution of BL in most patients is strikingly different from that seen in other malignant lymphomas. For example, in Ugandan patients, one or more quadrants of the jaw is involved in 50% of the patients (max occurrence at age 3 yr), and 4/5 women with BL have ovarian tumors (invariably bilateral) and 4%-10% men have testicular tumors (bilateral in one-third of cases). The most striking morphologic feature of IM is the wild hyperplasia of lymphoreticular elements. EBV may be identified in cells by the isolation of virus particles; virus capsid antigen (VCA); EBV-determined membrane, nuclear, and early antigens; and soluble complement-fixing antigen. Most African BL cases are EBV genome-negative. Antibodies to EBV-determined antigens can be detected in many patients with IM and BL, as can cell-mediated reactivity against EBV-infected cells and antibody-dependent lymphocyte cytotoxicity. The excellent response to chemotherapy and the long-term remission seen in a high proportion of BL patients could be related to host immunologic reactivity to the tumor cells. Raised antibody levels to EBV-associated antigens are also encountered in many patients with Hodgkin's disease and approx 40% of patients with chronic lymphocytic leukemia. However, the tumor cells in BL are almost invariably EBV genome-positive, whereas those in other lymphomas (except for 1 case of immunoblastic lymphadenopathy) are EBV genome-negative. New World, but not Old World, monkeys are also susceptible to EBV infection; they may develop lymphoma, a syndrome similar to IM, or no apparent infection. Although EBV and malaria are associated with BL, the possibility of a third factor in the etiology of the disease or the possibility that EBV and/or malaria are not etiologic factors must be considered. (218 refs)

- 79-3025 Use of Nude Mice for Tumorigenicity Testing and Mass Propagation.** (Eng) Shin, S. (Dept. Genetics, Albert Einstein Coll. Medicine, Bronx, NY 10461). *Methods Enzymol* 48: 370-379; 1979.

A review of procedures involved in the use of nude mice for tumorigenicity testing and mass propagation includes the source, maintenance, and breeding of nude mice; cellular tumorigenicity testing; testing for mycoplasma infection; mass production of cells in nude mice; and reestablishment of cell cultures from tumors. (22 refs)

- 79-3026 Carcinogenesis Effects of Combined Treatment: Immunologic Factors.** (Eng) Pomeroy,

T. C. (Div. Radiation Therapy, Univ. Texas Health Science Center, San Antonio, TX 78284). *Front Radiat Ther Oncol* 13: 194-214; 1979.

The role of immunologic alterations due to combined modality therapy in the development of malignant disease is reviewed. Spontaneous tumor formation and metastasis were enhanced in mice treated with cortisone acetate (CA). Manipulation of the reticuloendothelial system by CA, selected chemotherapeutic agents, and a nonspecific reticuloendothelial stimulant resulted in atrophy of the reticuloendothelial system. The degree of immune suppression also depends on the specific antigenicity of the individual tumor cells. Immune suppression by CA can interfere with the effects of radiation in tumor control, and the distribution of varying concentrations of chemotherapeutic agents within the tissues in a radiation field may become a critical factor. It appears that cortisone immunosuppression reduces the number of lymphomas that develop. Whereas the increase in solid tumors in transplant patients can be explained by immunosuppression, the increased incidence of reticulum cell sarcoma by any form of immunosuppression, including steroids, cannot be fully explained or correlated with the present data. It appears that the major effect of immune suppression on tumor incidence is a marked shortening of the latent period for tumor development. (40 refs)

- 79-3027 Do Macrophages Destroy Nascent Tumors?** (Eng) Adams, D. O. (Dept. Pathology, Duke Univ. Medical Center, Durham, NC 27710); Snyderman, R. *J Natl Cancer Inst* 62(6): 1341-1345; 1979.

The proposition that macrophages (MP's) play a central role in immune surveillance is discussed. Abundant evidence exists that MP's destroy neoplasms in vivo if the MP's can be attracted in large numbers by T or B lymphocytes and activated. MP's can also selectively recognize and destroy neoplastic cells in vitro. They bind tumor cells to their surface more than they bind normal cells and to a greater extent than nonactivated MP's bind either normal or neoplastic cells. It is proposed that tissue MP's recognize small clones of newly developed tumor cells, cluster about them, and destroy the nascent tumor to effect surveillance. The extremely small burden of tumor cells is recognized and destroyed by the MP's without need of amplification by other components of the immune system. The available data support but do not controvert the hypothesis that MP's exert surveillance. The development of a neoplasm does not abrogate the idea of surveillance. Clinically apparent neoplasms may be those that have developed the means to subvert MP functions. Evidence exists that tumors and carcinogens directly depress the function of MP's, and the ability of chemical carcinogens and tumor promoters to suppress MP function may be necessary to their carcinogenic potential. - 79-3028 Cancer after Cardiac Transplantation (Letter to Editor).** (Eng) Goldsmith, A. E. (Natl. Cancer Cytology Center, Melville, NY); Ryan, G. F.; Joseph, A. B. *Br Med J* 1(6171): 1146-1147; 1979.

Various animal models in which malignant lymphoma develops as a late sequel of transplantations in the absence of exogenous immunosuppressants are discussed. Chronic antigenic stimulation appears to be a possible common factor. Only lymphoid neoplasms developed, despite the grafting of four different tissues—lymph node, mammary gland, skin, and bone marrow. Bone marrow was the only tissue that did not induce lymphoma in its recipients, even following exposure to a nonphysiological environment. This raises the question whether the T lymphocytes in the graft tissues are involved in the malignant processes in these animal models. (5 refs)

- 79-3029 Immunosuppression and Malignant Disease.** (Eng) Penn, I. (Dept. Surgery, Univ. Colorado Sch. Medicine and Veterans Admin. Hosp., Denver, CO 80220). *Compr Immunol* 4: pp. 223-237; 1978.

The markedly increased incidence of neoplasms in immunosuppressed organ transplant recipients is surveyed. Many of the tumors are low-grade lesions of the skin, lip, and uterine cervix, but almost 26% are highly lethal lymphomas, compared with a 3% incidence in the general population. The lymphomas occur at a young age (av 36 yr) and after a relatively short induction time following transplantation (av 23 mo). Hodgkin's disease is rare, the preponderant type of lymphoma being reticulum cell sarcoma. Many of these tumors have the morphologic features of antigen-activated lymphocytes and can be classified as 'immunoblastic sarcomas.' The CNS is involved in nearly half the organ homograft patients with lymphomas other than Kaposi's sarcoma, and, in many instances, the lesions are confined only to the brain and spinal cord. The homograft is involved by lymphoma in 21% of cases. The cause of the increased incidence of malignancies in organ homograft recipients is unclear, but a complex interplay of multiple factors is probably responsible. Depression of the immunosurveillance function of the lymphoreticular system or immunosuppressive agents alone are probably not responsible for the increased incidence of cancer. The possible role of viruses and chronic antigenic stimulation of the lymphoid system by foreign histocompatibility antigens of the homograft must be considered. (80 refs)

- 79-3030 Immunodeficiency Diseases and Malignancy.** (Eng) Spector, B. D. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, Minneapolis, MN 55455); Perry, G. S.; Good, R. A.; Kersey, J. H. *Compr Immunol* 4: pp. 203-222; 1978.

The relationship between immunodeficiency (ID) and malignancy is reviewed based on data from 227 cancer patients with diagnosed ID diseases. Seven ID states are represented: X-linked (Bruton's) hypogammaglobulinemia (HGG: 12 cases); IgA deficiency (13); IgM deficiency (7); variable ID (70); severe combined ID (11); ataxia-telangiectasia (79); and Wiskott-Aldrich syndrome (35). Lymphoreticular tumors represented 129/227 total malignancies, and they were the most prevalent neoplasms in 5/7 ID diseases; in the two exceptions, IgA deficiency and X-linked HGG, lymphoreticular tumors accounted for 31% and 33% of the total, respectively. Differences in malignancy patterns were found in the distribution of epithelial cancers and leukemias: with IgA deficiency, 54% of all cancers were epithelial, and leukemias comprised 58% of all reported cancers with X-linked HGG. The cancers showed unique sex- and age-related characteristics. Also, a surprisingly large number of these patients developed gastrointestinal malignancies, particularly stomach cancers. The distribution of cancers by age and primary site indirectly supports the conclusion that immunodeficient patients are at greatly increased risk for development of cancer, despite a shortened life-span (2-20 yr). Hypotheses of the mechanisms of oncogenesis involving the lymphoid system fall into at least two general categories: the immune system in persons with genetically induced ID's has an increased likelihood of establishing lines of malignant cells; and the immune system in these diseases has decreased ability to eliminate malignant cells as they develop. The possible role of immunologic surveillance mechanisms in the defence against malignant cells has become a matter of increasing skepticism. (76 refs)

- 79-3031 α -Chain Disease: A Possible Model for the Pathogenesis of Human Lymphomas.** (Eng) Seligmann, M. (Lab. Immunochemistry and Immunopathology (INSERM U 108), Res. Inst. on Blood Diseases, Hopital Saint-Louis, Paris 10, France); Rambaud, J. C. *Compr Immunol* 4: pp. 425-447; 1978.

Various aspects of α -chain disease (CD), a proliferative disorder of B lymphoid cells involving primarily the IgA secretory system, are reviewed, along with its possible use as a model for the pathogenesis of human lymphomas. CD appears to proceed in two stages: the early stage is characterized by a possible nonmalignant diffuse and extensive plasma cell infiltration; the later stage is characterized by overt malignancy and supervening immunoblastic lymphoma. The diagnosis of CD relies entirely on laboratory studies, including immunochemical analysis of serum proteins. CD involves the production of molecules consisting of incomplete heavy α chains and no L chains. The striking and unexpected electrophoretic heterogeneity of these presumably monoclonal proteins may be related to their high carbohydrate content and tendency to polymerize. CD may involve a primary internal

deletion followed and obscured by a secondary proteolysis of limited degree. Intestinal CD usually presents with a severe malabsorption syndrome characterized by chronic diarrhea, steatorrhea, abdominal pain, and vomiting. Hepatosplenomegaly and peripheral lymphadenopathy are rare at presentation. Tetany is observed frequently, and it may be the major presenting symptom. The intestinal lesions of CD usually predominate in the duodenum and jejunum. There is also a less common respiratory form of the disease. Most CD patients are 10-30 yr old, and the male:female ratio is 3:2. Most patients originated from and had been living in areas with a high degree of infestation by intestinal microorganisms and were exposed to poor hygiene conditions in low socioeconomic circumstances. Most diffuse 'Mediterranean lymphomas' probably represent the late malignant phase of CD. Environmental factors providing a local and protracted antigenic stimulation may play an important role in the pathogenesis of the disease. Predisposing genetic factors may also exist, and the postulated environmental antigenic stimulus might be associated with an underlying immunodeficiency. (55 refs)

- 79-3032 Ecotaxis, Ecotaxopathy, and Lymphoid Malignancy: Terms, Facts, and Predictions.** (Eng) de Sousa, M. (Sloan-Kettering Inst. Cancer Res., New York, NY 10021). *Compr Immunol* 4: pp. 325-359; 1978.

The relationship of ecotaxis and ecotaxopathy to lymphoid malignancy are reviewed. Ecotaxis is the capacity of mature lymphomyeloid cells to arrange themselves in microenvironments of the peripheral lymphoid organs. For both T and B cells, ecotaxis involves circulation from blood to lymph and includes passage through large nonlymphoid capillary filters in the lungs and liver and slow penetration through distinct territories of the peripheral lymphoid organs. The position occupied by a cell in a lymphoid organ reflects a series of interactions with obvious and underlying neighbor cells. Thus, the accumulation or proliferation of one malignant cell type exemplifies a defect in these interactions as well as a defect in the malignant population itself. Since the spleen is one of the major sequestration sites of abnormal circulating cells, splenectomy will predictably help improve cell maldistribution. Ecotaxopathy is abnormal ecotaxis and is due to failure of circulating cells to migrate and occupy their normal environment. Experimental and human lymphoid malignancies are discussed to illustrate how progressive depletion of one lymphoid cell population in its normal environment could lead to the development of malignancy among its usual neighbors. These modified cell interactions may offer an explanation for some anomalies of immunologic function that are often associated with lymphoid malignancy. Any attempt to investigate a disease of the lymphoid system is incomplete if only one compartment is analyzed. The quality of therapy reflects understanding of disease pathogenesis. If the pathogenesis of lymphoid malignancy

is associated with the failure of neighboring cells to control the traffic and proliferation of malignant cells, therapy designed to eliminate the accumulating cells may only be temporarily beneficial. (151 refs)

- 79-3033 Immunodeficiencies Associated with Chronic Lymphocytic Leukemia and Non-Hodgkin's Lymphomas.** (Eng) Gupta, S. (Memorial Sloan-Kettering Cancer Center, New York, NY 10021); Good, R. A. *Compr Immunol* 4: 565-583; 1978.

The involvement of humoral immunity, cellular immunity, the phagocytic cell system, and amplifying systems in chronic lymphocytic leukemia and non-Hodgkin's lymphomas is discussed. Patients with non-Hodgkin's lymphomas often demonstrate an impairment of both cellular and humoral immunity that is usually minimal in early stages of localized disease, but becomes more pronounced with progression of the disease. Defects are usually more pronounced in patients with so-called reticulum cell sarcoma than in patients with lymphosarcoma. A depressed in vitro blastogenic response to mitogens is accompanied by abnormal glucose metabolism of lymphocytes. Reticuloendothelial phagocytic functions are generally intact. Familial studies demonstrate an apparent genetic relationship between immunologic abnormalities and susceptibility of lymphoid tissue to neoplasia. (135 refs)

- 79-3034 Experimental Models of Lymphoid Malignancies.** (Eng) Peterson, R. D. (Dept. Pediatrics, Univ. South Alabama Coll. Medicine, Mobile, AL 36617). *Compr Immunol* 4: pp. 81-127; 1978.

The experimental models of lymphoid malignancies are discussed. Thymic-type lymphomas are composed of apparently immature lymphocytes and are often characterized by abnormalities in chromosome number and morphology. The nonthymic lymphomas are often pleomorphic in cellular composition, and the reticulum cell sarcomas seem to preferentially involve the spleen, liver, and mesenteric lymph nodes. Lymphomas can be identified as belonging to the T- or B-cell category, although several experimental lymphoid malignancies do not show characteristics of either. Multigenic and nongenetic factors influence the process whereby a certain genetic configuration leads to a lymphoid malignancy; the malignancy may be incited by chemicals, viruses, radiation, or hormones. Tumor viruses may be acquired by an animal via vertical or horizontal transmission. Current knowledge of the molecular characteristics of these viruses exceeds knowledge of their relationship to tumors. The mechanism whereby radiation, or its associated oncornavirus, leads to lymphoma in experimental animals is also not known. There is some evidence that a virus is involved in the pathogenesis of chemically induced lymphomas. Various

REVIEW

manipulations of the immune system have led to increased incidences of lymphoid malignancies, and evidence exists that hormones can significantly influence such malignancies. At least some lymphoid malignancies appear to have hormonal dependence. Both the thymus and bursa (in chickens) appear to have central roles in the development of lymphoid malignancies. Although immunological mechanisms can deter the development and survival of malignant cells, the immune response may accelerate tumor growth in some situations. (591 refs)

- 79-3035 The Pathology of Lymphoreticular Neoplasms.** (Eng) Lukes, R. J. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA); Parker, J. W. *Compr Immunol* 4: pp. 239-279; 1978.

The pathology of lymphoreticular neoplasms is reviewed. Malignant lymphomas are now acknowledged to be neoplasms of the immune system, and they are related to the T- and B-cell systems and alterations in lymphocyte transformation. The neoplasms can be classified into five major groups: U cell (undefined), T cell, B cell, histiocytic, and Hodgkin's disease (cell of uncertain origin). A multiparameter investigative approach to the redefinition of these disorders as related to the T- and B-cell systems is outlined. Studies of over 300 cases of non-Hodgkin's lymphomas and related leukemias revealed that the majority (approx 85%) marked as T cells (20%) or B cells (65%). The exceptions were some of the acute lymphocytic leukemias (ALL's) and a rare case of apparently true histiocytic neoplasm. The cytomorphology of the various types was predictive of their T- and B-cell nature, but the reliability of this approach was dependent on carefully collected and prepared histologic sections and an experienced observer. The data obtained, and those of other investigators, permitted the identification of several new homogeneous cytological types that are emerging as clinical-morphologic-immunologic entities. These include the convoluted T-cell lymphoma-leukemia that interrelates with T-cell ALL, the plasmacytoid lymphocytic lymphoma commonly associated with monoclonal gammopathies, and the cerebriform T-cell lymphoma associated with Sezary's syndrome and mycosis fungoides. (93 refs)

- 79-3036 Clonal Origin of Human Tumors.** (Eng) Fialkow, P. J. (Medical Genetics Section, Medical Service, Veterans Admin. Hosp., Seattle, WA 98195). *Annu Rev Med* 30: 135-143; 1979.

Studies of the neoplasms that arise in patients with mosaicism provide important insights into stem cell relationships and factors involved in the initiation and progression of the tumors. At present, genetic marker approaches to the study of tumor development are essentially limited to

neoplasms that either synthesize immunoglobulin or arise in glucose-6-phosphate dehydrogenase (G-6-PD) heterozygotes. G-6-PD studies in chronic myelocytic leukemia (CML), polycythemia vera (PV), and idiopathic myeloid metaplasia with myelofibrosis have shown that these disorders involve pluripotent hematopoietic stem cells, and they suggest that at the time of diagnosis, the disorders probably have a clonal origin. However, fibroblasts cultured from the marrows of such patients do not arise from the abnormal stem cell clones. Although there is no evidence for residual normal committed granulocyte stem cells in CML, there are normal, but suppressed, stem cells in PV. Most benign and malignant tumors have been found to have a clonal origin at the time of examination, but one case of colon carcinoma, some invasive carcinomas of the cervix, some spontaneous parathyroid adenomas and multiple neurofibromatosis appear to have a multicellular origin. The malignant putative viral disease Burkitt's lymphoma is of clonal origin, whereas the benign viral growth "veneral" wart is of multicellular origin. Virus-infected cells appear to give rise to a malignant clone only if one or more additional events occur. (20 refs)

- 79-3037 Psoriasis and Cancer.** (Eng) Shuster, S. (Dept. Dermatology, Univ. Newcastle upon Tyne, Newcastle upon Tyne NE1 4LP, England); Chapman, P. H.; Rawlins, M. D. *Br Med J* 1(6168): 941-942; 1979.

It is hypothesized that the low incidence of skin cancer in psoriasis patients is due to a decreased capacity of psoriatic skin to metabolize carcinogens. Although psoriasis is treated by the topical application of tars, which are carcinogenic, and with ultraviolet B radiation, which is a major cause of skin cancer in healthy people, no increase in skin cancer incidence has been reported in chronic psoriasis. Epidermis from psoriasis patients shows reduced basal and induced aryl hydrocarbon hydroxylase (AHH) activity, both in the lesions and in lesion-free skin. If the hypothesis is correct, it would provide strong support for the idea that epidermal AHH activity is a major determinant of the development of skin cancer. The hypothesis also raises the possibility that the incidence of systemic cancer may be lower in psoriasis patients if the impaired AHH activity in psoriatic skin is shared by other tissues. Since psoriasis is probably transmitted as a simple dominant trait, it may have persisted because it confers a genetic advantage; ie, the decreased AHH activity of psoriatic skin, which reduces the incidence of cancer of the skin and perhaps of other organs. (15 refs)

- 79-3038 Premalignant Lesions of the Stomach.** (Eng) Gedigk, P. (Inst. Pathology, Univ. Bonn, Bonn, W. Germany); Bechtelsheimer, H.; Mueller-Wallraf, R. *Isr J Med Sci* 15(4): 405-409; 1979.

The histopathogenesis of the three major types of gastric carcinoma—intestinal, diffuse, and indeterminate—is reviewed. The gastric mucosa responds to any sustained irritation or damage with a proliferation of glandular neck cells and, eventually, a progressive decrease in differentiation (metaplasia) and the formation of intestinal-type glands. The rapidly transforming cells of the glandular neck are the probable site of neoplastic mutation, leading to persistent histologic abnormality. Long-lasting mucosal damage leads to a replacement of normal resting glandular cells by actively proliferating ones. With increased and continuing proliferative activity, carcinomatous polypoid protrusions may develop. Intestinal transformation usually involves only one of the many branches of the pyloric glands. Continuous growth and lack of cellular loss by shedding may lead to the formation of cysts deep in the mucosa and, occasionally, the submucosa. Invasive carcinoma eventually develops from these cysts. The four early stages of intestinal carcinoma belong to the category of intestinal metaplasia. Stage 3 is a borderline cancerous lesion and Stage 4 represents a high probability of carcinoma; Stage 5 represents the classic intestinal type of gastric carcinoma. The initial lesion in the development of a diffuse carcinoma is an atypical transformation of the lower part of the glandular neck (glandular neck dysplasia). The signet ring cell subtype starts with the development of clusters of cells in the glandular neck; in the anaplastic subtype, the detaching carcinoma cells of the glandular neck dysplasia are undifferentiated. The genesis of the early stages of indeterminate gastric carcinoma is not known. (52 refs)

- 79-3039** Some Leads to the Etiology of Cancer of the Large Bowel. (Eng) Hill, M. J. (No affiliation given). *Surg Annu* 10: 135-149; 1978.

Large bowel cancer is common in Western countries and is relatively rare in developing countries. It appears to be related to diet, particularly to meat or fat. Evidence from population studies in various parts of the world and from a retrospective case-control study supports the hypothesis that the Western diet results in a high concentration of bile acids in the large bowel and that these acids are metabolized by the gut bacteria to carcinogens or cocarcinogens. (88 refs)

- 79-3040** Epidemiology of Primary Neoplasms of Lymphoid Tissues in Animals. (Eng) Hardy, W. D. (Lab. Veterinary Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY 10021). *Compr Immunol* 4: pp. 129-180; 1978.

The occurrence of lymphoid tumors in animals is reviewed. The etiology of many animal lymphosarcomas (LSA's) is unknown, and the only etiological agents that have been discovered to date are viruses. The oncogenic RNA viruses

(oncornaviruses) can be transmitted vertically via the genes or horizontally by contagion. Avian and mammalian cells are resistant to superinfection with, and replication of their own endogenous oncornaviruses. Endogenous and exogenous oncornaviruses of cats and nonhuman primates can be distinguished serologically, and only the exogenous oncornaviruses induce LSA's in these species. Herpesviruses are the only DNA viruses associated with lymphoid tumors. They can be transmitted by contagion or transplacentally, but apparently not genetically. The epidemiology of naturally occurring LSA in mollusks, fish, amphibians, reptiles, chickens, mice, rats, hamsters, guinea pigs, cattle, sheep, horses, swine, dogs, cats, and primates is discussed. When possible, the incidence, clinical findings, tissues involved, etiology, epidemiology, seroepidemiology, prevention, and public health aspects of LSA's in each species are reviewed. Application of the findings to human LSA's is briefly considered. (250 refs)

- 79-3041** Epidemiology of Lymphoreticular Malignancies in Man. (Eng) Vianna, N. J. (Cancer Control Bureau, New York State Dept. Health, Albany, NY 12237). *Compr Immunol* 4: pp. 181-201; 1978.

Aspects of the epidemiology of lymphoreticular malignancies in humans are reviewed. International and regional variations in the incidence patterns of these diseases, particular Burkitt's lymphoma (BL), suggest that environmental factors may be important in their etiology. Lymphomas appear to be most prevalent among the more prosperous members of society and more common in urban than rural dwellers. In the US, men are affected more often than women, and marital status appears to influence the frequency of Hodgkin's disease (HD) specifically. Much lower rates were recorded among young married women than among young unmarried women or young men regardless of marital status. However, marital history had no apparent relevance to the frequency of HD among older population groups irrespective of their sex. The frequency and anatomical site of various lymphomas apparently differ geographically. Although Epstein-Barr virus and malarial parasites appear to play an etiologic role in BL, neither seems to be essential to the occurrence of the neoplasm. Demonstration of disease aggregates suggests that environmental factors, and possibly infectious factors, may contribute to the etiology of HD. Prior tonsillectomy may also be a predisposing factor. There is considerable evidence to indicate that immunoregulatory deficits contribute to the pathogenesis of autoimmunity, which in turn is coincidentally related to lymphoreticular malignancy. There is also limited evidence of a relationship between certain connective tissue disorders and various lymphoreticular malignancies. With the possible exception of multiple myeloma, the incidence of lymphoreticular malignancies is considerably lower in blacks than in whites. In view of the reported association between certain histocompatibility antigens and HD, consideration must be

REVIEW

given to the fact that the frequency of some antigens differs markedly among whites and blacks. In one study, it was suggested that the incidence of HD in several ethnic groups correlates significantly with the gene frequency of HLA-A1 and 8 antigens. The HLA system or some closely related genetic system might modulate the effects of environmental factors, and a similar interaction might hold for other malignant lymphomas. (143 refs)

- 79-3042 **Epidemiology of the Leukaemias in Africa.** (Eng) Fleming, A. F. (Dept. Haematology, Ahmadu Bello Univ., Zaria, Nigeria). *Leuk Res* 3(2): 51-59; 1979.

The epidemiology of acute lymphatic, acute myeloid, chronic myeloid, and chronic lymphatic leukemia in Africans is reviewed. Conditions commonly seen in adult Africans that feature a great excess of mature lymphocytes include the tropical splenomegaly syndrome, gross lymphoid hyperplasia (possibly preceding the development of lymphoma), and chronic lymphatic leukemia. (58 refs)

- 79-3043 **Studies of Respiratory Cancer in High Risk Communities.** (Eng) Blot, W. J. (Environmental Epidemiology Branch, NCI, Landow Bldg., 3C07, Bethesda, MD 20014); Fraumeni, J. F. *J Occup Med* 21(4): 276-278; 1979.

The contribution of routinely collected cancer mortality data to the search for causes of respiratory cancer is reviewed. Between 1950 and 1969, the highest lung cancer mortality rates in the US were clustered in coastal areas of the south; rates were also high in metropolitan centers in the northeast and midwest. Since it is unlikely that smoking patterns caused all of the geographic variations in incidence, other factors, including occupational exposure, probably played some role. Mortality tended to be higher in counties with chemical, petroleum, paper manufacturing, and shipbuilding industries. Nasal tumors were significantly more frequent in areas with high proportions of furniture makers and petroleum refineries. These findings agree with similar findings in other countries. Case-control interview studies showed a relative risk associated with employment in shipyards of 1.6; the relative risk was increased to 2.4 among employees who were heavy smokers. Information supplied by next-of-kin was in good agreement with that supplied by the patient. Epidemiologic investigations of this type should help to identify the lung cancer risk factors prevailing in various parts of the US. (24 refs)

- 79-3044 **Non-toxic Goitre.** (Eng) Hennemann, G. (Erasmus Univ., Medical Faculty, Dykzigt

Hosp., Rotterdam, Netherlands). *Clin Endocrinol Metab* 8(1): 167-179; 1979.

The possible etiological factors, epidemiology, development, clinical features, thyroid function, and management of nontoxic goiter are reviewed. This condition may be defined as a sporadically occurring benign diffuse or multinodular enlargement of the thyroid of unknown etiology that is not associated with apparent abnormal hormone secretion. (62 refs)

- 79-3045 **Conclusions.** (Eng) Truswell, A. S. (No affiliation given); Asp, N. G.; James, W. P.; MacMahon, B. *Nutr Cancer* 1(2): 104-105; 1979.

Conclusions reached during a symposium on nutrition and cancer are summarized. Different dietary factors appear to be associated with cancer of the gastrointestinal tract, liver, and, possibly, the urinary bladder. There is also evidence for an indirect association between the level and type of nutrition and cancers of the breast and uterine endometrium. The level of nutrition and/or dietary fat probably predisposes to breast cancer by changing the hormone balance. Cancer of the large intestine is related to the Western diet and is correlated epidemiologically to total fat intake. Some epidemiological evidence suggests that beef consumption is correlated with large intestinal cancer; frying or broiling could produce a carcinogenic product, but the evidence is not firm. Evidence associating rectal cancer with beer consumption is inconclusive. The incidence of stomach cancer has decreased in all the industrial countries. Salt-cured and smoked foods could lead to this cancer as a result of nitrosamine formation in the stomach from nitrites. Vegetables and fruits appear to exert a protective effect, possibly because of the antioxidant effect of vitamin C. Moldy food contaminated with fungal toxins can be carcinogenic; this is unusual in countries with an efficient food industry. In general, avoidance of obesity, lower consumption of total fat, and a larger intake of fiber are recommended. (no refs)

- 79-3046 **The Cause of Species Differences in Mammary Tumorigenesis: Significance of Mammary Gland DNA Synthesis.** (Eng) Nagasawa, H. (Pharmacology Div., Natl. Cancer Center Res. Inst., Chuo-ku, Tokyo, Japan). *Med Hypotheses* 5(4): 499-509; 1979.

The causes of the species differences in mammary tumorigenesis are discussed. The incidence of mammary tumors varies from none in pigs and sheep to 100% in selected strains of mice, and there are also variations in the pattern of development and progression of the tumors. Development and progression are controlled by both genetic and environmental factors. Among the latter are hormones, mammary tumor virus (MTV) in some strains of mice, immune mechanisms, and diet. However, there is

no clear explanation for the observed species differences in mammary tumorigenesis. It appears that the longer the total period of low mammary gland DNA synthesis, the smaller the risk of mammary malignancy. It is hypothesized that species differences in mammary tumorigenesis may relate to intrinsic differences between species in the rate of normal mammary gland DNA synthesis under physiological conditions and/or in response to external stimuli. Differences in mammary gland DNA synthesis in response to pituitary grafting or prolactin in rats and mice might be partly due to MTV as well as to intrinsic species differences. (28 refs)

- 79-3047 Big ACTH and Bronchogenic Carcinoma.** (Eng) Yalow, R. S. (Solomon A. Berson Res. Lab., Veterans Admin. Hosp., Bronx, NY 10468). *Annu Rev Med* 30: 241-248; 1979.

The potential role of ACTH determinations in the diagnosis and management of patients with bronchogenic carcinoma is reviewed. 'Big' ACTH (larger and more acidic than the usual peptide hormone) is often a major component of plasma and tumor ACTH in patients with ectopic Cushing's disease. Its biological activity is <4% of its immunologic activity. ACTH is frequently detected in tissue samples of carcinoma primary to or metastatic from the lung but not in tumors metastatic to the lung. The concentration in adenocarcinoma is generally significantly lower than that in epidermoid carcinoma. ACTH is not detectable in normal human, dog, or rabbit lung, but it is found in some pathologic lung tissue, even in the absence of invasive carcinoma. If elevated values of plasma ACTH are derived from tumor ACTH, the tumor must be large, have a higher than minimally detectable hormone concentration, or be more active in secretion of the hormone than the pituitary. False-negative results can be obtained from lung tumors that do not meet these criteria. Also, in some patients, plasma ACTH apparently is not derived solely from tumor ACTH. False-positive results can result from the sporadic release of pituitary ACTH, even in normal subjects, and a significant fraction of false positives may be found among heavy smokers, particularly those with chronic obstructive pulmonary disease. The data suggest that determination of plasma ACTH in a mass screening program for early detection of lung carcinoma is of limited value, primarily because of this overlap between patients with invasive carcinoma and heavy smokers. (19 refs)

- 79-3048 Ectopic ACTH In Carcinoma of the Lung.** (Eng) Yalow, R. S. (Veterans Admin. Hosp., Bronx, NY 10468). *Prog Cancer Res Ther* 11: 209-216; 1979.

The use of radioimmunoassay to detect increases in plasma ACTH in patients with carcinoma of the lung is reviewed. ACTH is found in a high percentage of bronchial adenomas and carcinomas primary to or metastatic from

the lung, but not in other carcinomas metastatic to the lung. About one-third of pancreatic tumors also contain ACTH. The concentrations in lung adenocarcinomas are generally significantly less than those in squamous cell carcinomas. Although ACTH is not detectable in normal lung tissue, it is found in at least some pathologic lung tissue in the absence of invasive carcinoma; a significant number of these false-positive results might be found among heavy smokers. False negatives are most likely to be found among patients considered suitable for surgical resection rather than among those with more extensive or virulent disease. In one study, patients with extensive disease appeared to exhibit elevated ACTH levels more frequently than those with limited disease. In another study, 21/24 patients with untreated carcinoma of the lung had afternoon plasma ACTH concentrations >150 picogram/ml, the upper limit demonstrated in only 6% of the control group. Before determinations of ACTH can be used as part of a mass screening program for early detection of lung carcinoma, it will be necessary to determine that elevations are due to cancer and not simply to heavy smoking. The applicability of this procedure for differentiating between primary and metastatic disease and for monitoring the effects of surgical resection, chemotherapy, and radiotherapy has yet to be determined. (16 refs)

- 79-3049 Placental Proteins in Bronchogenic Carcinoma.** (Eng) Broder, L. E. (Comprehensive Cancer Center State of Florida, Univ. Miami, Miami, FL 33152); Rosen, S. W.; Weintraub, B. D.; Sussman, H. H.; Muggia, F. M.; Hansen, H. H.; Primack, A. *Prog Cancer Res Ther* 11: 217-225; 1979.

The use of placental proteins as cancer markers, especially in patients with bronchogenic carcinoma (BC) is reviewed. Human chorionic gonadotropin (hCG) has been found in the sera of 12% of a large series of cancer patients, 9% of 147 patients with BC, and in 4% of 201 patients with inoperable BC. hCG is composed of two dissimilar subunits, and inefficient combination and differential production of these subunits by clonal strains derived from the same tumor have been observed. Human placental lactogen (hPL) was found in approx 5% of 295 cancer patients and in 2% of the 201 inoperable BC patients. Placental alkaline phosphatase (PAP) was also found in 2% of the latter. The presence of each marker peptide (eg, hCG, hPL, and PAP) in the inoperable patients was independent of the other two, and the concentrations varied independently when more than one was found in a single patient. Serum marker concentrations have occasionally shown discordances during chemotherapy: marker concentrations fell despite increases in tumor size. The usefulness of these markers hinges on the fact that they are normally undetectable or present only in low concentrations in the plasma. Placental markers may prove useful in the location of primary neoplasms and in the identification of cerebral metastases. The biochemical basis for their expression by nonplacental neoplastic cells remains to be determined. (31 refs)

CHEMICAL CARCINOGENESIS

- 79-3050 **Monitoring Environmental Exposures with Semen Assays.** (Eng) Gledhill, B. L. (Lawrence Livermore Lab.). *Energy Technol Rev* 7-16; 1979.

Analysis of animal and human semen based on conventional parameters (ie, sperm count, motility, and morphology) may be useful in assessing human spermatogenic injury induced by environmental agents. Data from studies in mice suggest that induced sperm abnormalities result from mutations of the genes that control spermatogenesis. The F_0 (examination of semen from exposed animals) and F_1 (examination of the offspring of exposed animals) tests in mice could be used to screen chemical and physical agents commonly or uniquely found in the workplace. Animal and human data suggest that lowered sperm count, reduced sperm motility, and increased sperm abnormalities are correlated with reduced fertility and the likelihood of spontaneous abortions and stillbirths. Flow cytometric techniques are being developed to determine induced changes in the shape and DNA content of human sperm as part of a screening procedure for monitoring human occupational exposure. The detection of clastogenic effects in human sperm will require improvements in resolution, but the technique looks promising. It may even be possible to automate the chore of visually scoring percent abnormal sperm through the microscope. (14 refs)

- 79-3051 **Dose Response to Cancerogenic and Mutagenic Treatments.** (Eng) Totter, J. R. (Inst. Energy Analysis, Oak Ridge Associated Univs., P.O. Box 117, Oak Ridge, TN 38730); Finamore, J. *Environ Int* 1(5): 233-244; 1978.

Thirty-seven dose-response curves obtained following exposure of animal and plant material to carcinogenic chemicals or low-LET (linear energy transfer) ionizing radiation were gathered from the literature. These curves, along with one obtained following exposure to a nutritional factor, were analyzed. The data show that there is no response that is unique to low-LET radiation nor is there one that is special for chemical carcinogens. Both responses can be depicted as a family of curves that is commonly used to describe biochemical reactions. Only two parameters need to be determined for each species to compare their respective responses to the agent (and, presumably, to extrapolate these data to very low doses). One of the parameters must be largely population dependent, ie, related to gene distribution, but the other is related to the nature of the agent and is probably little affected by the treatment. It is not clear how much alteration in response

may accompany marked differences in modes of administration. The dose-response data from the 38 experiments are displayed in a logarithmic plot on a single graph. Values of the two parameters and the doses and responses needed to construct the graph are tabulated. The mathematical treatment of the published data shows an unexpected universality of biological behavior that may be helpful in extrapolating experimental data to humans. (33 refs)

- 79-3052 **Ozonation of Mutagenic and Carcinogenic Alkylating Agents, Pesticides, Aflatoxin B_1 , and Benzidine in Water.** (Eng) Caulfield, M. J. (Lobund Lab., Dept. Microbiology, Univ. Notre Dame, Notre Dame, IN 46556); Burleson, G. R.; Pollard, M. *Cancer Res* 39(6, part 1): 2155-2159; 1979.

Kinetic studies of the effect of ozonation on the mutagenicity of selected chemicals in water were performed with the use of the *Salmonella*-microsome assay. The mutagenicity of certain pesticides, including bis(2-chloroethyl)amine and sodium azide, was rapidly inactivated by ozonation (0.5-1.5 min), but that of other alkylating agents, such as β -propiolactone, propanesultone, and N-methyl-N'-nitro-N-nitrosoguanidine was unaffected by ozone treatment. Ozone also rapidly inactivated the mutagenicity of aflatoxin B_1 (0.5 min). Three chemicals were converted to direct mutagens by ozone treatment. Under certain conditions, dimethylhydrazine could be converted to a mutagen that was stable for weeks. A similar chemical, 2-hydroxyethylhydrazine, was converted to an unstable mutagen that was inactive after 24 hr at room temperature. When benzidine was treated with ozone, there was a transient increase in mutagenicity that was lost after longer treatment with ozone. (26 refs)

- 79-3053 **5-Methylcytosine Content of Nuclear DNA During Chemical Hepatocarcinogenesis and in Carcinomas Which Result.** (Eng) Lapeyre, J. N. (Section Experimental Pathology, M. D. Anderson Hosp. and Tumor Inst., Univ. Texas System Cancer Center, Houston, TX 77030); Becker, F. F. *Biochem Biophys Res Commun* 87(3): 698-705; 1979.

To examine the relationship between DNA methylation and malignancy, measurements were made of 5-methylcytosine levels in the nuclear DNA of normal Sprague-Dawley rat liver and of premalignant and malignant hepatic tissues induced by diethylnitrosamine (DEN)

and acetylaminofluorene (AAF). DNA from premalignant nodules and primary hepatocellular carcinomas (HCC's) induced by AAF and from primary HCC's induced by DEN was undermethylated by 20%, 45%, and 32.5%, respectively. A 12.5% hypomethylation occurred during the DNA synthesis phase of hepatic regeneration. To better determine the effect of cell proliferation on methylation, DNA synthesis in 21-hr regenerating rat liver was determined and compared with that in two transplantable HCC lines. DNA synthesis, hence, the cell proliferation rate, was approx 33% and 39% greater in the 21-hr regenerating liver than in the two respective HCC lines. Despite this, the transplantable HCC's demonstrated significantly less 5-methylcytosine than the regenerating liver. There was a relative 49% and 59% hypomethylation in the transplantable HCC DNA. It is suggested that an aberration in endogenous DNA methylation may occur during neoplastic transformation. (45 refs)

79-3063 Chromosome Lateral Asymmetry: A Sensitive Assay for Screening Teratogenic Agents. (Eng) Tucci, S. M. (Dept. Anatomy, Albany Medical Coll., Albany, NY); Skalko, R. G. *J Environ Pathol Toxicol* 2(3): 625-632; 1979.

The effects of in utero administration of three teratogens on the frequency of lateral asymmetry in mouse embryo chromosomes were determined. Pregnant albino ICR mice were administered single ip embryotoxic doses of bromodeoxyuridine (2,000 mg/kg), hydroxyurea (250 mg/kg), or mitomycin C (0.5-10.0 mg/kg) on day 10 of gestation. Embryos were removed 4 hr later, and a cell suspension was prepared and cultured in the presence of colcemid. Metaphase chromosome spreads were subjected to standard G-banding procedures, and the occurrence and frequency of lateral asymmetry (unequal banding of sister

CHEMICAL CARCINOGENESIS

chromatids) was monitored. Embryotoxic levels of all three teratogens increased the number of asymmetries/karyotype. For mitomycin C, the increase was dose-dependent. (24 refs)

79-3067 The Mitochondrial Activation of Sulfate and Arsenate and Their Role in Carcinogenesis. (Eng) Hadler, H. I. (Dept. Chemistry and Biochemistry, Southern Illinois Univ., Carbondale, IL 62901); Cook, G. L. *J Environ Pathol Toxicol* 2(3): 601-612; 1979.

A study demonstrating that sulfate and arsenate can substitute for phosphate in the transitory uncoupling of rat liver mitochondria induced by hydrazine when β -hydroxybutyrate is the substrate is presented. Although hydrazine (400 μ M), sulfate (1.5 mM), or arsenate (200 μ M) alone did not induce transitory uncoupling, hydrazine combined with either sulfate or arsenate did cause uncoupling; this effect was blocked by rutamycin. The inception of stimulated respiration by hydrazine and sulfate was slowed by 150 μ M AMP and completely blocked by ADP, ATP, pyrophosphate, and Mg^{2+} (all at 150 μ M). Benzene sulfonate (1.5-6.0 mM) did not uncouple mitochondria either alone or in combination with hydrazine (300-600 μ M), and EDTA (5-10 mM) did not produce an EDTA-dependent hydrazine uncoupling when tested with 300-600 μ M hydrazine. Since sulfate enhances the carcinogenicity of certain carcinogens, these results expand the experimental confluence between oxidative phosphorylation and chemical carcinogenesis and also explain at least in part the

"toxic" effects of sulfate. Arsenate may also enhance carcinogenicity. The data are compatible with epidemiological studies implicating some role in carcinogenesis for sulfate and arsenate. (35 refs)

79-3068 Detection of the Mutagenic Activity of Lead Chromate Using a Battery of Microbial Tests. (Eng) Nestmann, E. R. (Mutagenesis Section, Environmental and Occupational Toxicology Div., Dept. Natl. Health and Welfare, Ottawa, Ontario K1A 0L2, Canada); Matula, T. I.; Douglas, G. R.; Bora, K. C.; Kowbel, D. J. *Mutat Res* 66(4): 357-365; 1979.

The potential mutagenicity of the carcinogen lead chromate was tested in the *Escherichia coli* PolA⁺/PolA⁻ survival test; the *Salmonella*/microsome His⁺ reversion assay; the *E. coli* Trp⁺ reversion test as a plate assay; the *E. coli* Gal⁺ forward mutation test; and the *Saccharomyces cerevisiae* assay for mitotic recombination. Lead chromate was mutagenic in *Salmonella* and in *Saccharomyces* and was thus identified as a microbial mutagen by this battery. Metabolic activation by a rat liver homogenate mixture (S9) was not required for the manifestation of mutagenic activity. The most statistically significant, positive result was found with a supplementary assay, the *E. coli* fluctuation test. To determine whether the lead ion and/or the chromate ion was responsible for the mutagenicity, lead chloride and chromium trioxide (chromic acid) were also tested. In *E. coli* fluctuation tests, the ranges of max mutagenicity for chromium trioxide and lead chromate overlapped at the concentration 10^{-5} M, whereas lead chloride showed no mutagenicity and little lethality at concentrations up to 10^{-3} M. Thus, the chromate ion apparently is responsible for the mutagenicity of lead chromate. (16 refs)

79-3070 Determination of Nickel in Urine and Plasma by Atomic Absorption Spectrophotometry. (Cze) Tichy, M. (Institut hygieny a epidemiologie, Centrum hygieny prace a nemoci z povolani, Srobarova 48, 100 42 Prague 10, Czechoslovakia); Horejsi, M. *Prac Lek* 30(9): 337-340; 1978.

Nickel levels in the urine and serum of healthy subjects not exposed to nickel were determined by atomic absorption

spectrophotometry. The urinary clearance averaged 22 $\mu\text{g}/1/24$ hr. The mean plasma level was 2.7 $\mu\text{g}/100$ ml. (21 refs)

79-3071 Effect of Induced Skin Cancer on the Concentrations of Some Trace Elements in the Mouse.

(Eng) Mangal, P. C. (Dept. Biophysics, Panjab Univ., Chandigarh-160014, India); Verma, K. B. *Indian J Med Res* 69: 290-295; 1979.

The concentrations of the trace elements Se, Cr, Fe, Co, Zn, Sc, Rb, Cd, Ag, and Sb in normal and malignant mouse skin were studied using a neutron activation technique without chemical separation. Skin cancer was induced in female Swiss mice by sc injection of 20-methylcholanthrene (0.4 mg). The concentrations of Cr, Ag, and to a lesser extent, Sb were higher and the concentrations of Se and, to a lesser extent, Fe, Zn, and Rb were lower in the tumor tissue than in normal skin. Co, Cd, and Sc levels were similar in both tissues. It is not clear whether the changes in the concentrations of certain trace elements were a cause or effect of neoplastic growth. (11 refs)

79-3073 Reduction in Mutagenicity of Cigarette Smoke Condensate by Added Sugars. (Eng) Sato, S.

(Biochemistry Div., Natl. Cancer Center Res. Inst., 5-1-1 Tsukiji, Chuo-ku, Tokyo 104, Japan); Ohka, T.; Nagao, M.; Tsuji, K.; Kosuge, T. *Mutat Res* 60(2): 155-161; 1979.

The effects of adding glucose, fructose, galactose, sorbitol, sucrose, and lactose to high- and low-tar cigarettes on the mutagenicity of their smoke condensates (SC's) were studied using *Salmonella typhimurium* strains TA100 and TA98 with and without metabolic activation. Using TA98 with metabolic activation, the lowest mutagenicities observed after addition of the sugars per milligram of SC were 37% (high-tar cigarettes) and 22% (low-tar cigarettes) of that of the SC from untreated cigarettes. Although the sugars increased the total amounts of SC, they decreased the mutagenicities of the total condensates, the lowest values being 35% (high-tar cigarettes) and 36% (low-tar cigarettes) of that of the SC from untreated cigarettes. Using TA100 with metabolic activation, decreases in both specific and total mutagenicities of the SC's of high-tar cigarettes were observed with all the sugars tested except galactose and sucrose. Glucose, fructose, or sorbitol decreased the specific mutagenicity of low-tar cigarette

condensates, and glucose and fructose also reduced their total mutagenicity. The effects of the sugars were more marked with TA98 than with TA100, and of the sugars tested, fructose and sorbitol had the greatest effects. Without metabolic activation, the sugars had no effect on the mutagenicity of the SC's. (21 refs)

79-3074 Effect of Tobacco Smoke on the Metabolism of Rat Lung. (Eng) Hamosh, M. (Dept.

Physiology and Biophysics, Georgetown Univ. Sch. Medicine and Dentistry, Washington, DC 20007); Shechter, Y.; Hamosh, P. *Arch Environ Health* 34(1): 17-23; 1979.

The effect of cigarette smoke on the uptake and metabolism of ^3H -palmitate, ^3H -leucine, U^{14}C -glucose, and ^{14}C -glucosamine was studied using slices of rat lung. Male Sprague-Dawley rats were exposed daily for 30 days to University of Kentucky research cigarettes [brands 1A1 (25 mg tar, 0.3 mg nicotine) or 1R1 (30 mg tar, 2.2 mg nicotine)], in the Walton smoking machine on two schedules: one cigarette 2x/day or three cigarettes 2x/day (7 puffs cigarette). One group of rats served as intact controls, and another was introduced to the machine but was not exposed to smoke. All animals were wt-matched at the beginning of the experiment (180 ± 5 g); machine-control rats gained 25% less wt, 1A1-exposed rats 40% less, and 1R1-exposed rats 26%-40% less than controls. Exposure to tobacco smoke had no effect on palmitate uptake and synthesis of phospholipids. Exposure to 1A1 cigarettes caused a 25% increase in $^{14}\text{CO}_2$ production and a 30% higher incorporation of glucose into lipids. Exposure to 1R1 cigarettes had no effect on glucose metabolism. Protein synthesis was 30% lower in 1R1-exposed rats, and glycoprotein synthesis increased twofold in both 1A1- and 1R1 exposed rats. At present, there is no satisfactory explanation for these observations (43 refs)

79-3076 Cellular Immunity in Asbestosis. (Eng) Lange, A. (Dept. Occupational Diseases, Inst. Internal Diseases, Medical Sch., 50-367 Wroclaw, Poland); Smolik, R.; Chmielarczyk, W.; Garncarek, D.; Gielgier, Z.

Arch Immunol Ther Exp (Warsz) 26(1-6): 899-903; 1978.

CHEMICAL CARCINOGENESIS

The involvement of lymphocyte malfunction in the pathogenesis of asbestosis was investigated in 271 asbestos workers. Asbestosis and positive antinuclear antibody (ANA) titers were encountered significantly more frequently among workers who responded in delayed-hypersensitivity skin tests to tuberculin and/or streptokinase-streptodornase (SK-SD) than among those who responded to neither antigen. The proportion of lymphocytes lacking RBC and complement receptors was higher in workers with asbestosis than in those without the disease and higher in ANA-positive subjects. Assay for migration inhibitory factor showed impairment in the generation of this factor following stimulation of lymphocytes with SK-SD, phytohemagglutinin (PHA), or purified protein derivatives of tuberculin in subjects with asbestosis. Study of lymphocyte transformation showed an impaired response to lower doses of PHA and concanavalin A in asbestosis-positive, ANA-positive, and asbestosis-negative, ANA-positive workers. The data suggest that impairment of cell-mediated immunity is closely linked to the pathogenesis of asbestosis, which is associated with a high risk of cancer. (12 refs)

79-3077 Establishment and Characterization of a Human Mesothelioma Cell Line (Meeting Abstract). (Eng) Ohnuma, T. (Mount Sinai Sch. Medicine, New York, NY 10029); Wolman, S. R.; Daum, S. M.; Holland, J. F. *Proc Am Assoc Cancer Res* 20: 162; 1979 (no refs)

79-3078 Discontinuities in Dose Response Curves from Toxicological Tests. (Eng) Anderson, R. L. (Procter & Gamble Co., Miami Valley Labs., Cincinnati, OH). *Household & Personal Products Industry* 16(4): 92,94; 1979.

Nonlinear dose-related shifts in urinary pH and increases in urinary calcium, magnesium, and phosphorus excretion occurred in rats fed sodium saccharin in doses of up to 7.5%. These and further observations suggested that saccharin influences the normal metabolic pathways for nitrogen excretion and disturbs the acid/base balance. It is possible that shifts in the cellular environment produce changes in urinary tract cells via physical forces and not via chemically induced changes in cellular constituents. (1 ref)

79-3079 Studies on the Mutagenic Properties of Bleaching Effluents. (Eng) Eriksson, K. E. (STFI, Box 5604, Swedish Forest Products Res. Lab., S-114 86 Stockholm, Sweden); Kolar, M. C.; Kringstad, K. *Svensk Papperstidning* 82(4): 95-104; 1979.

The existence of mutagenic substances in effluents from the bleaching of softwood and hardwood kraft and sulfite pulps was determined using the histidine-requiring mutant *Salmonella typhimurium* strain TA1535. Effluents from the first-stage bleaching of softwood and hardwood kraft and softwood sulfite pulp with chlorine or mixtures of chlorine and chlorine dioxide-containing compounds contained mutagens. All other bleaching effluents were non-mutagenic. The compounds responsible for the mutagenic effects were relatively unstable when stored under neutral conditions, and they were highly unstable when stored under alkaline conditions. The results do not allow an assessment of the risks involved in releasing the mutagenic effluents into rivers and lakes. (7 refs)

79-3080 Safety Evaluation of Toothpaste Containing Chloroform. III. Long-Term Study in Beagle Dogs. (Eng) Heywood, R. (Huntingdon Res. Centre, Huntingdon, England); Sortwell, R. J.; Noel, P. R.; Street, A. E.; Prentice, D. E.; Roe, F. J.; Wadsworth, P. F.; Worden, A. N.; Van Abbe, N. J. *J Environ Pathol Toxicol* 2(3): 835-851; 1979.

Groups of eight male and female beagle dogs were given 15 or 30 mg/kg/day of chloroform (CF) in a toothpaste base po (in gelatin capsules) on 6 days/wk for 7.5 yr, followed by a 20- to 24-wk recovery period. Groups of 16 males and females received vehicle only, and 7 dogs of each sex remained untreated. Eleven of the 96 dogs died during the study, only 2 of these being in the CF-treated groups. The only significant toxic response during treatment was a moderate rise in SGPT levels; they reached a peak in the sixth year of the study and probably corresponded to minimal liver damage. Few palpable growths were noted while the dogs were alive. Fatty cysts were seen in the liver of several dogs at postmortem; they could possibly be associated with CF treatment, but the distribution of nodular changes in the liver was not obviously dose-related. A small number of macroscopic and microscopic neoplasms were seen; one dog in each CF-treated group had a malignant tumor, but there were no tumors in the liver or kidney of any dog. Overall, exposure to CF in a toothpaste base was not associated with any effect on the incidence of any kind of neoplasm. From this and related studies in mice and rats, it is concluded that repeated exposure to 3.5% CF in toothpaste is unlikely to result in any hazard to human health. (21 refs)

79-3081 Safety Evaluation of Toothpaste Containing Chloroform. II. Long Term Studies in Rats. (Eng) Palmer, A. K. (Huntingdon Res. Centre, Huntingdon, England); Street, A. E.; Roe, F. J.; Worden, A. N.; Van Abbe, N. J. *J Environ Pathol Toxicol* 2(3): 821-833; 1979.

The results of a preliminary 13-wk po toxicity study of chloroform (CF) in a toothpaste base, conducted with the use of Sprague-Dawley rats, are reported, along with the results of two longer-term studies. Significant changes in serum enzyme and certain hematological parameters were seen at the higher dose levels (150 and 410 mg/kg/day) in the range-finding study. Intercurrent disease made it necessary to terminate the first long-term experiment prematurely after 1 yr. No evidence of serious toxicity was recorded. In the second long-term experiment, groups of 50 cesarian-derived specific pathogen-free Sprague-Dawley rats received 60 mg/kg/day CF in a toothpaste base or the vehicle only by gavage on 6 day/wk for 80 wk; they were observed for an additional 15 wk. CF-treated rats of both sexes survived longer than the controls, although both groups had a high incidence of nonneoplastic respiratory and renal disease. Female rats consistently had decreased plasma cholinesterase levels, shown to be related to activity against butyrylcholine but not acetyl- β -methylcholine. Tumors of various sites were seen in 39% of CF-treated rats of both sexes examined histologically, compared with 38% of vehicle controls. There were no treatment-related effects on the incidence of liver or kidney tumors. Malignant mammary tumors occurred in more treated than control rats, but the difference was not statistically significant. Thus, long-term CF treatment had no adverse effect on survival and did not significantly influence time of onset, malignancy, or location of tumors. (6 refs)

- 79-3082 Safety Evaluation of Toothpaste Containing Chloroform. I. Long-Term Studies in Mice.** (Eng) Roe, F. J. (Huntingdon Res. Centre, Huntingdon, England); Palmer, A. K.; Worden, A. N.; Van Abbe, N. J. *J Environ Pathol Toxicol* 2(3): 799-819; 1979.

Studies were performed to determine whether exposure of mice to chloroform (CF) at dose levels 113 and 400 times the level ingested by humans using toothpaste containing 3.5% CF, but less than those producing severe liver damage, predisposed to cancer of the liver or any other site. CF was administered to several strains of mice by gavage in a toothpaste base or in arachis oil, in doses of 17 or 60 mg/kg/day on 6 days/wk for 80 wk. Control groups were left untreated or given vehicle only. In general, there were more survivors in CF-treated groups than in the controls. In C57BL, CBA, and CF/1 males, treatment was associated with no adverse effect on the incidence of any type of neoplasm or any other parameter. In males but not females of strain ICI, and in doses of 60 mg/kg/day but not 17 mg/kg/day, exposure to CF in toothpaste was associated with an increased incidence of epithelial tumors of the kidney. This effect was more pronounced in mice given 60 mg/kg/day CF in arachis oil. This treatment was also associated with a higher incidence and severity of non-neoplastic renal disease. The mechanisms underlying the peculiar strain- and sex-specific susceptibility of ICI male mice remain obscure; spontaneous renal tumors were also

seen in vehicle control mice, and possible ways in which this tendency may be enhanced by CF treatment are discussed. At the dose levels tested, no adverse effect was seen in the liver and there was no increased incidence of liver tumors, even in the higher liver tumor-susceptible CBA strain. At the 17-mg/kg/day level no excess of renal tumors was seen, even in males of the susceptible ICI strain. (21 refs)

- 79-3083 Carcinogenicity of Hexachlorocyclohexane (BHC) in Pure Inbred Swiss Mice.** (Eng) Kashyap, S. K. (Natl. Inst. Occupational Health, Meghani Nagar, Ahmedabad-380016, India); Nigam, S. K.; Gupta, R. C.; Karnik, A. B.; Chatterjee, S. K. *J Environ Sci Health [B]* B14(3): 305-318; 1979.

The carcinogenicity of technical grade benzene hexachloride (BHC: 100 ppm in the diet for 80 wk, 10 mg/kg by po intubation for 80 wk, or 0.25 mg painted on the skin twice weekly for 80 wk) was investigated in inbred Swiss mice. The BHC-treated and control mice did not differ with respect to survival rate, body wt, or growth rate, although the control animals consumed more food throughout the experimental period. Signs of BHC intoxication included convulsions, circling behavior, drooping ears, and corneal opacity. The incidence of tumors was significantly higher among the mice given BHC po than among the controls and nonsignificantly higher among the mice painted with BHC. The incidence of liver tumors was higher among males than females, and females were more susceptible to lymphoreticular tumors. Tumors seldom occurred at more than one site. Most of the liver tumors in the BHC-treated groups were hepatocellular carcinomas, whereas the controls developed only hepatomas and hemangiomas. The incidence of lung tumors, primarily well-circumscribed adenomas, was low, and few tumors developed in other sites. The results point out the high incidence of liver and lymphoreticular tumors induced by BHC given po (with the diet or through intubation). (7 refs)

- 79-3084 Residues of Chlorinated Pesticides in Mother's Milk and in the Serum of Their Babies.** (Cro) Bazulic, D. (Odsjek za pesticide, Zavod za zastitu zdravlja SRH, Zagreb, Yugoslavia); Kipic, D.; Stampar-Plasaj, B.; Jeric, J.; Bujanovic, V.; Juzbasic, N. *Arh Hig Rada Toksikol* 29(2): 125-128; 1978.

Serum and milk samples from 27 nursing mothers and serum samples from their babies were analyzed for organochlorine pesticide residues. α -Benzene hexachloride (α -BHC: 77.8 ppb), β -BHC (150 ppb), 1,1-dichloro-2,2-bis(p-chlorophenyl) ethylene (p,p'-DDE: 1,537 ppb), 1,1,1-trichloro-2-(o-chlorophenyl)2-p-chlorophenylethane (o,p'-DDT: 42.8 ppb), 1,1-dichloro-2,2-bis(p-

chlorophenyl) ethane (p,p'-DDD: 59.6 ppb), and 1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane (p,p'-DDT: 256 ppb) were found in the milk samples. The corresponding concentration in maternal sera were 6.8 ppb and α -BHC, 13.1 ppb for β -BHC, 13.8 ppb for p,p'-DDE, 10.7 ppb for o,p'-DDT, 5.5 ppb for p,p'-DDD, and 34.4 ppb for p,p'-DDT. The ratio of the serum concentrations in the mother to that in the baby was 0.95 for α -BHC, 0.64 for β -BHC, 1.18 for p,p'-DDE, 0.31 for o,p'-DDT, 0.72 for p,p'-DDD, and 1.70 for p,p'-DDT. (5 refs)

79-3085 Carcinomas and Other Lesions of the Liver in Mice Ingesting Organochlorine Pesticides. (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD 21701). *Clin Toxicol* 13(2): 231-256; 1978.

The effects of po organochlorine pesticide treatment on the livers of mice were studied. Carcinomas of the liver, often multiple, were induced at high incidence rates in mice given dieldrin, aldrin, heptachlor, heptachlor epoxide, kepone, lindane, chloroform, chlordane, or carbon tetrachloride. Increased incidences of liver carcinomas were also seen in mice given chlorobenzilate, mirex, DDT [1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane], methoxychlor, or endrin. There were occasional metastases to the lungs; however, a careful search for metastases was generally not carried out. Well-, moderately well-, and poorly differentiated hepatocellular and cholangiocellular carcinomas were observed, the metastatic tumors being predominantly hepatocellular carcinomas. Hemangioendothelial sarcomas, leiomyosarcomas, and reticulum cell sarcomas were rarely observed. Focal cirrhosis was occasionally seen in mice given heptachlor or heptachlor epoxide, and it was severe in animals given large doses of carbon tetrachloride or chloroform. Hepatic vein thrombi were occasionally present in mice given heptachlor, heptachlor epoxide, dieldrin, aldrin, or chlorobenzilate, and focal hepatic necrosis was sometimes seen. (78 refs)

79-3088 The Mutagenicity of Halogenated Alkanols and Their Phosphoric Acid Esters for *Salmonella typhimurium*. (Eng) Nakamura, A. (Natl. Inst. Hygienic Sciences, Kamiyoga 1-18-1 Setagaya, Tokyo); Tateno, N.; Kojima, S.; Kaniwa, M.; Kawamura, T. *Mutat Res* 66(4): 373-380; 1979.

Nine halogenated alkanols, nine corresponding tris(haloalkyl)phosphates, and two bis(2,3-dibromopropyl)phosphate salts were evaluated for mutagenicity toward *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537, and TA1538, with and without a rat liver microsome metabolic activation system (S9 mix). Most of the test samples were mutagenic toward TA100 and TA1535, but not TA98, TA1537, and TA1538. In general, the mutagenic activities of the phosphates obtained in the presence of the S9 mix were greater than those obtained in the absence of the mix. Among the phosphates, several structure-activity relationships were found: (1) the bromoalkyl derivatives were more mutagenic than the corresponding chloroalkyl derivatives, (2) the β -haloethyl derivatives were more mutagenic than the γ -halopropyl derivatives, (3) the phosphates having adjacent β - and γ -halogen atoms in the alkyl moiety, [eg, tris(2,3-dibromopropyl)phosphate (tris-DBPP)] were particularly potent mutagens, and (4) the branched carbon chain reduced mutagenicity in spite of the presence of β -halogen atoms [eg, tris(1-bromomethyl-2-bromoethyl) phosphate]. However, these relations did not necessarily apply to the halogenated alkanols. It is concluded that the metabolic activation pathway via haloalkanol to mutagens must not be common to all of the tris-DBPP-like phosphates. (12 refs)

79-3101 DNA Fragmentation in Some Organs of Rats and Mice Treated with Cycasin. (Eng) Cavanaugh, M. (Dept. Pharmacology, Univ. Genoa, I-16132 Genoa, Italy); Parodi, S.; Taningher, M.; Bolognesi, C.; Sciaba, L.; Brambilla, G. *Br J Cancer* 39(4): 383-390; 1979.

The effect of cycasin (50-400 mg/kg, po or ip) on the elution rate of DNA (an increase being indicative of DNA damage) from liver, lung, kidney, and colon mucosa was studied in male C57BL/6 mice and male Wistar rats. In rats killed 4 hr after po cycasin, dose-dependent DNA damage was found in the liver and, to a lesser extent, in the kidney and colon mucosa; the lung appeared insensitive to the drug. The max effect was seen by 4 hr for the liver, by 2-4 hr for the kidney, and by 4-6 hr for the colon mucosa. In mice killed 6 hr after po cycasin or 4 hr after ip cycasin, liver DNA showed a dose-dependent increase in elution rate, the max effect occurring by 6-12 hr. Cycasin had practically no effect on the DNA of lung, kidney, or colon mucosa. DNA repair up to 18 hr appeared to be incomplete in both rats and mice. No evidence of cellular necrosis was seen in any organ 24 hr after cycasin treatment. Human EUE cells exposed to 1 or 2 mg/ml cycasin for 1 hr showed

CHEMICAL CARCINOGENESIS

increased DNA elution rates without single-strand breaks. The increase was amplified by metabolic activation. The data indicate that cycasin is a peculiar type of procarcinogen that depends on a glucosidase for its activation to the biologically active aglycone methylazoxymethanol. (20 refs)

79-3111 Forward Mutation Assays Using Bacteria and 8-Azaguanine. (Eng) Castellino, S. (Gruppo Mutagenesi Ambientale, Montedison S.p.A., Divisione Ricerche e Sviluppo e Istituto Ricerche, Carlo Erba, Milan, Italy); Lorenzetti, R.; Ravenna, L.; de Carneri, I. *Ecotox-icol Environ Saf* 2(3/4): 277-299; 1978.

The incidence of forward mutations employing 8-azaguanine-resistance and reverse mutations using histidine independence was compared in several strains of *Salmonella typhimurium*. The test compounds, which cause missense or frameshift mutations in the indicator strains, were N-methyl-N'-nitro-N-nitrosoguanidine, ethyl methanesulfonate, methyl methanesulfonate, β -propiolactone, streptozotocin, hycanthone, 9-aminoacridine, and 2-nitrofluorene. All eight compounds gave positive results with *S. typhimurium* strain TA1535 in the forward mutation assay. Six compounds were also positive with TA98 and TA100; 9-aminoacridine and 2-nitrofluorene were the exceptions. The presence of the R factor in strains TA98 and TA100 may prevent these two compounds from being mutagenic in this assay. All eight compounds gave positive results in the reverse mutation tests in strains with genetic alterations specific for the action of each compound. Selection for histidine independence generally produced higher mutation frequencies than selection for 8-azaguanine resistance, but it required a minimum of three strains for the eight compounds. It is concluded that neither of the methods has marked advantages over the other in detecting mutagenicity. (8 refs)

- 79-3112 Effect of Cell Growth Rate and Dose Fractionation on Chemically-induced Ouabain-resistant Mutations in Chinese Hamster V79 Cells.** (Eng) Lankas, G. R. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL 60439). *Mutat Res* 60(2): 189-196; 1979.

The effect of reducing the cell growth rate on the number of ouabain-resistant mutants induced by N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) was studied using Chinese hamster V79 cells. Cells grown in medium with 10% fetal calf serum (FCS) grew faster than those grown in medium with 2% FCS. The reduced growth in 2% FCS was greater after treatment of the cells with 0.5 µg/ml MNNG than after treatment with 1.5 µg/ml. At 0.5 µg/ml MNNG, cell survival was greater and the mutation frequency lower in the slowly growing cells than in the faster growing cells. At 1.5 µg/ml MNNG, growth rate reduction did not affect cell survival or mutation frequency significantly. Two consecutive 0.75 µg/ml doses of MNNG were as toxic as 1.5 µg/ml given for half the time (1 hr), but the number of mutants induced by the split dose was significantly greater than the number induced by the single 1.5-µg/ml dose. There was an exponential decline in the percent of surviving cells and an exponential increase in mutation frequency as a function of duration of exposure to 48 µg/ml methylazoxymethanol acetate. The results demonstrate that growth rate affects the mutation frequency in V79 cells treated with low doses of chemical mutagens. (17 refs)

- 79-3114 Selectivity of the Excision of Alkylation Products in a Xeroderma Pigmentosum-derived Lymphoblastoid Line.** (Eng) Altamirano-Dimas, M. (Dept. Microbiology, Univ. Chicago, Chicago, IL 60637); Sklar, R.; Strauss, B. *Mutat Res* 60(2): 197-206; 1979.

The ability of Raji cells and human lymphoblastoid cells (XPA-3, derived from a group C xeroderma pigmentosum patient) to excise O⁶-methylguanine (OMG) and 3-methyladenine formed by reaction of the cells with N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) or methyl methanesulfonate (MMS) was studied. Both Raji and XPA-3 cells were competent in excision repair synthesis after treatment with MMS or MNNG. However, although Raji cells removed significant amounts of OMG from their DNA after treatment with MNNG, XPA-3 cells removed

relatively little. Both cell lines removed 3-methyladenine rapidly. The single gene *Escherichia coli* mutants *uvrA* and *uvrB*, which are UV-sensitive because of a defect in excision repair, were able to excise MNNG-induced OMG adducts, indicating the excision of this compound was not due to operation of the UV endonuclease system. Treatment of XPA-3 cells with MNNG resulted in numerous single-strand breaks in the DNA. The results support the hypothesis that base excision/apurinic repair and nucleotide excision proceed independently. It is predicted that xeroderma lines should be more sensitive than normal cells to the mutagenic effect of compounds such as MNNG, which produce considerable amounts of OMG. (24 refs)

79-3120 Multiple Hepatic Cysts Induced Experimentally by N-Methyl-N'-nitro-N-nitrosoguanidine in the Rat. (Fre) Justrabo, E. (Laboratoire d'Anatomie Pathologique, Faculte de Medecine, 21000 Dijon, France); Michiels, R.; Martin, M. S.; Martin, F. *Ann Gastroenterol Hepatol (Paris)* 15(1): 9-16; 1979.

The induction of multiple hepatic cysts by N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) was studied in 158 male and female BD IX, BN, Lewis, Wistar and Lewis (female) x BN (male) hybrid rats. Starting at age 6-8 wk, the animals received drinking water containing 83 mg/liter of MNNG for 7 mo. The surviving animals were sacrificed when the daily examination revealed hepatomegaly, ascites, wt loss, bloody stools, or bronchopneumopathy. One hundred and six gastric carcinomas and 84 intestinal tumors were found, and they were almost always associated with multiple hepatic cysts. The cyst induction rates were 100% in the BDIX, BN, and hybrid rats, 84% in the Lewis males, 94% in the Lewis and Wistar females, and 81.8% in the Wistar males. The cysts ranged from a few to 15 mm in diameter. They were filled with a lemon-yellow or turbid liquid, they had thin translucent walls, and they were closely clustered near the portal tracts. Ultrastructural study revealed the biliary nature of the cysts. The histological picture resembled that of polycystic disease in humans. (34 refs)

79-3121 Effect of the Carcinogen MNNG and Experimental Ulcer on Gastroduodenal Epithelial Proliferation in the Rat (Meeting Abstract). (Eng) Quimby, G. F. (Univ. Massachusetts Medical Sch., Worcester, MA); Eastwood, G. L. *Gastroenterology* 76(5, part 2): 1221; 1979 (no refs)

79-3122 Mutagenicity and Carcinogenicity of N-Methyl-N'-nitro-N-nitrosoguanidine. I. Induction of Chromosome Aberrations and Mitotic Anomalies in Chinese Hamster Ovary Cells. (Eng) Bemping, M. A. (Biomedical Res. Center, Norfolk State Coll., Norfolk, VA 23504). *J Environ Pathol Toxicol* 2(3): 633-656; 1979.

The spectrum of chromosome aberrations induced by N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) in Chinese hamster ovary (CHO) cells is reported. Cultured CHO cells were exposed to 0.25-2.0 µg/ml MNNG for 24 hr or 6 days. For cytological studies, CHO cells were treated for 24 hr and allowed a 24-hr recovery period prior to analysis; for cytotoxicity evaluations, cells were treated for 6 days followed by a 6-day recovery period. With respect to the cytotoxic effect of MNNG, there was a semilogarithmic decrease in the number of colonies formed with an increase in MNNG concentration. Cytologically, the chemical caused both structural and numerical chromosome anomalies,

and the incidence of each aberration type was influenced by MNNG concentration. Karyomorphological analysis of CHO cells treated for 24 hr and fixed after four cell cycles showed a varied chromosome constitution ranging from 18 to 54. Changes in chromosome structure arising from breaks and/or exchanges were of chromatid type. The distribution of breaks along the length of the chromosomes and among chromosomes showed that no chromosome segment or chromosome was preferentially susceptible to the clastogenic effects of MNNG. MNNG-induced chromosome rearrangements, such as ring configurations, exchanges, and dicentrics, exceeded such cytological errors as fragments and pulverizations. In a descending order of magnitude, the induced structural rearrangements were ring chromosomes, triradials, quadriradials, and dicentrics. (26 refs)

79-3123 Induction of Intestinal Metaplasia and Carcinoma in the Glandular Stomach of Rats by N-Alkyl-N'-nitro-N-nitrosoguanidines. (Eng) Matsukura, N. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Kawachi, T.; Sugimura, T.; Nakadate, M.; Hirota, T. *Gann* 70(2): 181-185; 1979.

The effects of 0.34 mM solutions of four homologs of N-alkyl-N'-nitro-N-nitrosoguanidine (N-alkyl-NNG) on gastric histology were studied in male Wistar rats that received one of the four compounds in the drinking water for 12 mo. The rats were killed 18 mo following initiation of the experiment. The incidence of intestinal metaplasia (IM) in the glandular stomachs of rats that received N-propyl-NNG, N-butyl-NNG, N-isobutyl-NNG, N-pentyl-NNG, or pure water was 100%, 50%, 44%, 17%, and 11%, respectively. The incidence of IM in the first group was significantly higher than that in the other groups ($0.001 < P < 0.05$). In all groups, the metaplastic glands were found most frequently in the proximal pyloric region. Adenomas and well-differentiated adenocarcinomas were found in the pyloric region of 2/7 surviving rats treated with N-propyl-NNG; no tumors occurred in any of the other groups. These findings support human studies showing that there is a correlation between the incidence of IM and well-differentiated adenocarcinoma. Thus, some human food carcinogens may cause IM and adenocarcinoma. (12 refs)

79-3124 Catalytic Effect of *p*-Nitrosophenol on the Nitrosation of Diethylamine. (Eng) Walker, E. A. (International Agency Res. Cancer, 69008 Lyon, France); Pignatelli, B.; Castegnaro, M. *J Agric Food Chem* 27(2): 393-396; 1979.

The kinetics of the nitrosation of diethylamine in water at 37 C was determined by gas chromatography. The reaction

was second-order with respect to nitrite, with a pH-independent rate constant of $0.87 \times 10^5 \text{ M}^{-2} \text{ sec}^{-1}$. The reaction catalyzed by p-nitrosophenol (p-NP) over a wide pH range was first-order with respect to nitrite, amine, and p-NP. A mechanism for this reaction is suggested. p-BP could be formed in the digestive tract by the reaction of phenol with nitrite ingested in saliva. Assuming complete nitrosation of the phenol, the rate of formation of nitrosodiethylamine under in vivo conditions could increase by a factor of about 140. Although this calculation is based on a model system and is an oversimplification, since there would be inhibiting factors as well as possible additional catalytic effects by other nitrosophenols, it illustrates a potential promoting effect on the in vivo formation of nitrosamines due to constituents in food. (25 refs)

79-3125 Dibenzofuran-free Aroclor 1254 as a Promoter of Diethylnitrosamine (DNA) Hepatocarcinogenesis in Rats (Meeting Abstract). (Eng) Preston, B. D. (Univ. Wisconsin, Madison, WI 53706); Van Miller, J. P.; Moore, R. W.; Allen, J. R. *Proc Am Assoc Cancer Res* 20: 153; 1979 (no refs)

79-3126 Induction of Nasopharyngeal Carcinoma in Rats by Nitroso Compounds. (Jpn) Cancer Research Group (Hunan Medical Coll., Hunan, People's Republic China). *Kexue Tongbao* 23(12): 756-760; 1978.

Rats weighing 100-150 g were divided into two groups. Group I received diethylnitrosamine intranasally, by sc injection in the back, or by rectal administration. Some rats in this group were also treated im with vitamin B₁₂ or po with 5% glucose. Group II rats received nitroso compounds intranasally or by sc injection. A high percentage of Group I rats developed nasopharyngeal carcinoma; some also had liver cancer. The vitamin B₁₂- and glucose-treated rats had a higher incidence of nasopharyngeal tumors but a lower incidence of liver tumors. Group II rats had a high incidence of nasopharyngeal carcinoma but a low incidence of liver cancer. (no refs)

79-3127 The Effects of Ethanol, Glucose and Sucrose on Nitrosation of Secondary Amines Following Alkalization of Reaction Mixture. (Eng) Yamamoto, M. (Dept. Food Additives, Natl. Inst. Hygienic Sciences, 18-1 Kamiyoga 1-chome, Setagaya-ku, Japan); Yamada, T.; Tanimura, A. *J Food Hyg Soc Jpn* 20(1): 15-20; 1979.

Nitrosodiethylamine (NDEA) formation was stimulated when diethylamine (DEA) was reacted with sodium nitrite at pH 3 in the presence of ethanol (E), glucose (G), or sucrose (S), and then the mixture was alkalinized with NaOH to terminate the reaction. E, G, and S had no effect on

NDEA formation when the reaction was terminated with sulfamic acid. It is postulated that the nitrous acid ester formed from sodium nitrite and E, G, or S in acidic medium nitrosates DEA in alkaline medium. (15 refs)

- The metabolism of dimethylnitrosamine (DMN) to molecular nitrogen was investigated in rat and mouse liver microsomes. As a positive control, N₂ production from N-methyl-N-nitrosourea (NMU) was studied. N₂ was produced stoichiometrically from the spontaneous decomposition of NMU in phosphate buffer and was readily detected by gas chromatography. N₂ production from DMN was about 70% that of formaldehyde when either rat or liver microsomes were used. The stoichiometric production of N₂ from NMU decomposition and the fact that NMU and DMN are believed to generate a common intermediate, monomethylnitrosamine, support a proposed pathway in which DMN is metabolized to methyldiazonium ion, which rapidly decomposes to methyl carbonium ion and N₂; the carbonium ion, being an S_N1 type alkylating agent, may react with water, producing methanol, or with cellular nucleophiles, leading to toxicity and genetic alterations. - The effect of vegetable juices and milk, low-risk foods for gastric cancer, on the alkylation of 4-(p-nitrobenzyl)pyridine by N-methyl-N-nitrosourea (MNU) was studied to gain information about dietary factors for stomach cancer. A spectrophotometer was used to measure the absorbance of a mixture of MNU (7.2 micromoles) in 400 μ l of each test liquid before and after incubation at 37 C for 200 min. The juices and milk effectively decomposed MNU and consequently decreased its alkylating activity. The effectiveness (per dried materials) of the test liquids decreased in the order radish > cabbage > garden peas > lettuce > cucumber > celery > milk > tomato. The alkylating activity of N-methyl-N'-nitro-N-nitrosoguanidine was similarly reduced by the vegetable juices and milk. The results suggest that fresh vegetables and dairy products play an important role in stomach cancer prevention by reducing the alkylating properties of chemical carcinogens. (11 refs)

Four polycarpellary mutants were screened from the M_2 progeny of *Cajanus cajan*, whose seeds had been soaked in 0.03% nitrosomethylurea (NMU) for 14 hr prior to planting. All the mutants forming viable seeds bred true in the M_3 generation. At the 10- to 12-leaf stage, apical growth of the main shoot of the mutants was inhibited. All polycarpellary mutants had five types of flowers that exhibited an increase in the number of carpels. (6 refs)

- 79-3151 Distribution of O⁶-Methylguanine in Rat DNA Following Pretreatment In Vivo with Methylnitrosourea. (Eng) Chang, M. J. (Dept. Veterinary Pathobiology, Ohio State Univ., 1925 Coffey Road, Columbus, OH 43210); Webb, T. E.; Koestner, A. *Cancer Lett* 6(3): 123-127; 1979.

The possibility of a difference in the distribution of O⁶-methylguanine (O⁶-MG) within unique and repetitive DNA sequences of rat organs with different carcinogenic susceptibilities to N-methyl-N-nitrosourea (MNU) was investigated. Ten-day-old Sprague-Dawley rats were inoculated with MNU (80 µg/g ip), and brain, kidney, and liver were pooled 2 hr later. The unique and repetitive DNA fractions from each organ were separated, and the amount of O⁶-MG was determined chromatographically. There was little difference in the relative distribution of O⁶-MG between the unique and repetitive DNA sequences of all the organs examined. These results suggest that neoplastic transformation may involve not only mutations in the structural genes but also changes in the regulatory apparatus. Methylation of the O⁶-position of guanine in DNA occurred to similar extents in brain (the highest risk organ), kidney (of intermediate oncogenic susceptibility), and liver (the lowest risk organ). It is suggested that the significance of the formation of O⁶-MG to carcinogenesis will eventually be explained in terms of its persistence in specific DNA fractions. (16 refs)

79-3155 Thyroid Tumors in Rats from Tetramethylthiourea. (Eng) Stula, E. F. (Haskell Lab. Toxicology and Industrial Medicine, E.I. du Pont de Nemours and Co., Inc., Wilmington, DE 19898); Sherman, H.; Barnes, J. R. *J Environ Pathol Toxicol* 2(3): 889-906; 1979.

The results of long-term toxicity testing of tetramethylthiourea (TMTU), an accelerator for neoprene vulcanization, in rats are presented. TMTU was added to the diet of male and female ChR-CD rats for up to 2 yr at levels of 0, 30, and 300 ppm. Fifty rats of each sex were used at each dietary level. High-level males and females and low-level males had a lower body wt and consumed less diet than did the controls. A slight anemia was found in the high-level males and females. Polyuria of a low osmolality was found in high level males and females. Serum thyroxine was lower in high-level males and females than in controls. TMTU-related gross and histologic changes were detected only in the thyroids of high-level males and females. After 3 mo on the test diet, the thyroids were enlarged and dark on gross examination. Histologically, there was an increase in follicle lumen size, loss of colloid staining, hypertrophy and hyperplasia of follicular cells, plus hyperemia. These early lesions were diffuse in distribution. After 18-24 mo on the test diet, 8/29 female high-level rats developed follicular cell carcinomas; no such tumors were observed in 26 comparable controls ($p < 0.0005$). Although no metastases were found, capsular and vascular invasion by tumor cells was seen. TMTU was considered to be carcinogenic for the female rat under the conditions of this test. (16 refs)

79-3159 Comparative Carcinogenicity of Some Derivatives of Nitrosodi-n-propylamine in Rats. (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, P.O. Box B, Frederick, MD 21701); Taylor, H. W. *Ecotoxicol Environ Saf* 2(3/4): 421-426; 1978.

The carcinogenicity of nitrosodi-n-propylamine (NDPA), two β -oxidized derivatives, nitrosobis(2-hydroxypropyl)amine (I) and nitrosobis(2-oxypropyl)amine (II), and halogenated derivative, nitrosobis(2-chloropropyl)amine (III), was compared in female Sprague-Dawley rats. NDPA and compounds I and II were given in the drinking water at equimolar doses at concentrations of 90, 108, and 106 mg/liter, 5 days/wk, for 30, 50, and 30 wk, respectively. Compound III was given by gavage: 0.2 ml of a 34-mg/ml soln in olive oil 2x/2w for 20 wk. NDPA was the most potent carcinogen. Compound I had the least effect on survival and was a relatively weak carcinogen. The effectiveness of the chlorinated derivative was difficult to assess because of its toxicity. NDPA was a broadly acting carcinogen and induced a high incidence of tumors in the liver, nasal turbinates, and esophagus. The three derivatives appeared to be less broadly acting, eg, compound II only induced liver tumors. These results indicate that the hypothetical formation of oxygenated derivatives of NDPA in vivo is not a likely mechanism of carcinogenesis. (8 refs)

79-3163 N-Nitrosamines in the Diet of Experimental Animals. (Eng) Walker, E. A. (International Agency Res. Cancer, Lyon, France); Castegnaro, M.; Gričute, L. *Cancer Lett* 6(3): 175-178; 1979.

Eighty-seven samples of experimental animal feed were analyzed in four independent laboratories for the presence of chemical carcinogens. Volatile N-nitrosamines were found regularly, the most common being N-nitrosodimethylamine (90% of samples at levels of 1-10 µg/kg). The highest level found was 300 µg/kg for N-nitrosopiperidine, which represented one isolated case. Other N-nitrosamines detected included N-nitrosodiethylamine, N-nitrosodipropylamine, N-nitrosodibutylamine, and N-nitrosopyrrolidine. Since all animal experiments include control groups for which pathology is performed, it is suggested that collective analysis of the food in these experiments could provide data on effects in animals of exposure to low levels of N-nitrosamines. 79-3167 Distribution of Nitrogen-13 from Labeled Nitrate ($^{13}\text{NO}_3^-$) in Humans and Rats. (Eng) Witter, J. P. (Dept. Medical Microbiology, Univ. Wisconsin Medical Sch., Madison, WI 53706); Gatley, S. J.; Balish, E. *Science* 204(27): 411-413; 1979.

The body distribution of po (by gavage) or iv administered nitrate labeled with nitrogen-13 was studied in two human volunteers and conventional-flora rats. The data suggested that the body can act as a temporary reservoir of ^{13}N (a significant amount of this label would probably be in the form of NO_3^-); the ^{13}N passes beyond the upper small intestine (duodenum and jejunum) when ingested; biliary, pancreatic, or intestinal secretions may contribute to the pool of ^{13}N present in the lower small and large intestines; and bowel alterations (resection or strangulation) may enhance the influx of NO_3^- into the bowel contents. These observations indicate that depletion of body stores, the passage of nitrate down the gut, or the secretion of nitrate into the intestinal lumen may be a better explanation of the urinary, ileal, and fecal concentrations of nitrate and nitrite recently measured in humans than a bacterial nitrification reaction in the intestines. (12 refs)

79-3168 Nitrate and Nitrite. (Eng) Jagerstad, M. (Dept. Clinical Res., Univ. Hosp., Lund, Sweden); Kolar, K.; Nilsson, R.; Norden, A. *Scand J Gastroenterol Suppl* 14(52): 214-216; 1979.

The mean daily intake of nitrate and nitrite was determined in pooled samples of lyophilized and fat-free food homogenate powder representing 7-day diets consumed by a group of pensioners in a predominantly agricultural area in Sweden. The mean daily intake of nitrate was 499 ± 271 micromoles (µmol) for the men and 307 ± 118 µmol for the women. Corresponding values for nitrite intake were 58 ± 21 and 36 ± 14 µmol for the men and women, respectively. No specific disease could be related to the highest intakes of nitrite. The only person known to have a malignant disease had a nitrate intake of 412 µmol/day. The nitrate intake among the men was <1.1 mg/kg/day and among the women was <0.8 mg/kg/day. The nitrite intake was <0.08 mg/kg/day for both men and women. These values are well within the acceptable levels recommended by the World Health Organization. However, there could be a salivary supply of 6-10 mg nitrite per day, which, together with the dietary intake, might exceed the accepted safe level for sodium nitrite of 0.2 mg/kg/day. (11 refs)

79-3169 An Improved Method for Nitrite Extraction from Plants. (Eng) Klepper, L. A. (Dept. Agronomy, Univ. Nebraska, Lincoln, NE 68583). *J Agric Food Chem* 27(2): 438-441; 1979.

A method for extracting nitrites from plant tissues is

presented that results in recoveries that are higher than those obtained by aqueous extraction. The soln to be extracted is treated with methylene chloride (MeCl_2) or insoluble polyvinylpyrrolidone (PVP) prior to extraction with sulfanilamide/ α -naphthylethylenediamine/HCl reagent. The mean recovery from a variety of plants, including tea, avocado, sweet potato, apple, wheat, sweet potato, radish, potato, and soy bean, was 89%-95%. These recoveries represented increases ranging up to 69.8% over those obtained with aqueous extraction. The lowest nitrite recovery (69%) was obtained from apple leaves; because of the high concentrations of tannins and polyphenols in this tissue, extraction might have been more effective with the addition of larger amounts of PVP to the extraction medium. In most extractions, the result after centrifugation was a clear, aqueous, nitrite-containing supernatant above the PVP/ MeCl_2 portion. Thus, additions of MeCl_2 and insoluble PVP can protect nitrite from reactive substances during aqueous extractions for nitrite analyses. (12 refs)

79-3170 Chronic Toxicity of Sodium Nitrite in Mice with Reference to its Tumorigenicity. (Eng) Inai, K. (Second Dept. Pathology, Hiroshima Univ. Sch. Medicine, Kasumi 1-2-3, Hiroshima 734, Japan); Aoki, Y.; Tokuoka, S. *Gann* 70(2): 203-208; 1979.

The toxicity and possible tumorigenicity of sodium nitrite (NaNO_2) were studied in 8-wk-old ICR mice. The 6-wk toxicity study demonstrated that the max tolerated dose of NaNO_2 was 0.5%. Three groups of 100 mice each received drinking water containing 0.5, 0.25, or 0.125% NaNO_2 for 109 wk; 40 controls received drinking water alone. With increasing dose, the mice drank less water, but the amount consumed by those receiving 0.5% NaNO_2 was approx 3x greater than that consumed by those receiving 0.125%. Although the tumor incidence in each experimental group appeared to exceed 50% of the effective mice (ie, those surviving more than 18 mo or those that died with malignant tumor during the experiment), there was no evidence of a relationship between the concentration or total amount of NaNO_2 consumed and tumor incidence. Thymus, lymph node, or bone marrow tumors occurred in 27% of the male controls and 33% of the female controls. In the experimental animals, the incidence of these tumors ranged between 11% and 44%, with the highest incidences found in mice that received 0.125% NaNO_2 . Total tumor incidence (including hematopoietic, soft tissue, lung, liver, uterus, mammary gland, and 10 miscellaneous tumors) in the experimental animals was not significantly different from that in the controls, and tumor latency periods were similar in both groups. These results, together with the fact that the daily NaNO_2 dose in animals receiving the highest level was approx 3x that consumed by persons in the US, suggest that dietary NaNO_2 levels are not tumorigenic. 79-3174 Carcinogenicity of N-Nitroso Derivatives of N-Methylcarbamate Insecticides in Rats. (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, P.O. Box B, Frederick, MD 21701); Schmahl, D. *Ecotoxicol Environ Saf* 2(3/4): 413-419; 1978.

N-Nitroso derivatives of N-methylcarbamate insecticides were synthesized and tested for carcinogenicity in rats. Sprague-Dawley rats (6-8 wk old) were given 1.0 ml/kg of a 60-mg/ml soln of nitrosocarbaryl (NC) in corn oil 1x/wk by gavage for a total dose of 600 mg/kg. Nitrosocarbaryl (NCF), nitrosobaygon, and nitrosomethylphenylcarbamate (NMPC) were so toxic at equimolar doses that the experiment was restarted at one-fourth the dose for a longer period of time. Other rats were given 0.2 ml of a soln of nitroso compound in olive oil at a concentration equivalent to 25 mg NC/ml 1x/wk by stomach intubation for 10 wk. Nitrosoaldicarb, NCF, and NMPC were toxic at this dose rate and at half this rate as well. All of the nitroso-N-methylcarbamates were carcinogenic, with the target organ being the nonglandular stomach. Nitrosobaygon, NCF, and nitrosolandrin were the most potent carcinogens, and there was little difference among them. NC, nitro-Bux-ten, and nitrosomethomyl were weak carcinogens. NMPC induced fewer tumors than the other compounds because its toxicity was higher and fewer rats survived to develop tumors. It is concluded that the formation of nitrosomethylcarbamates by reaction of the parent insecticide with nitrite in the environment or stomach represents an increased carcinogenic risk. (11 refs)

- 79-3177 Effect of Implantation of Liver and Spleen Cells from Mature Parent Mice on Urethan Carcinogenesis in F₁ Hybrids. (Rus) Kraskovskii, G. V. (Inst. Genetics and Cytology, Minsk, USSR); Kagan, L. F. *Dokl Akad Nauk BSSR* 23(2): 176-179; 1979.

(Af x C57BL)F₁ female mice were inoculated with 10⁶ urethan (1.5 mg/mouse, ip) and, 1 day later, with 50 x 10⁶ lymphoid cells from C57BL mouse embryo liver. One month later, animals were inoculated ip with 50 x 10⁶ lymphoid cells from C57BL mouse embryo spleen. Implantation of liver cells alone did not change the incidence of urethan-induced lung adenomas (17.9%, vs 16.9% in mice exposed to urethan alone), but administration of spleen cells significantly decreased the incidence of lung adenomas (12.4%). (15 refs)

- 79-3178 Effect of Aluminium Chloride on Metabolism of 4-Nitroquinoline 1-Oxide. (Eng) Yamane, Y. (Faculty Pharmaceutical Sciences, Chiba Univ., 1-33, Yayoi-cho, Chiba 260, Japan); Ohtawa, M. *Gann* 70(2): 147-153; 1979.

Aluminum chloride (AlCl₃) was administered sc to male dd mice, and its effect on the activities of 4-nitroquinoline 1-oxide (4-NQO) 4-hydroxy-aminoquinoline 1-oxide (4-HAQO) reductases and the organ distribution of carcinogen(s) in mouse lung and liver were examined. AlCl₃ administration resulted in significant elevation of 4-NQO reductase and 4-HAQO reductase activities in both lung and liver, compared with the activities in control mice. Following the simultaneous administration of AlCl₃ and ¹⁴C-4-NQO, the distribution of radioactivity at 0.5 and 1 hr postadministration decreased in the lung but increased inversely in the liver. Radioactivity in the lung and liver 2 hr postadministration was not different from that in the controls. Simultaneous sc administration of ¹⁴C-4-NQO and AlCl₃ resulted in a decreased pulmonary distribution of 4-NQO and 4-HAQO but an increased distribution of the noncarcinogenic metabolites 4-aminoquinoline 1-oxide (4-AQO) and 4-hydroxyquinoline 1-oxide (4-OHQO). The

distribution of 4-aminoquinoline (4-AQ) and 4-hydroxyquinoline (4-OHQ) in the lung did not differ from that in the controls. The AlCl₃-induced decrease in the lung concentrations of 4-NQO and 4-HAQO may be a factor responsible for the suppression of lung carcinogenesis by AlCl₃. (13 refs)

- 79-3179 Mutagenic Effects of Sodium Azide in *Drosophila Melanogaster*. (Eng) Kambra, O. P. (Dept. Biology, Dalhousie Univ., Halifax N.S., Canada); Gollapudi, B. *Mutat Res* 66(4): 381-384; 1979.

The mutagenic effects of low-pH buffered solns of sodium azide (NaN₃, injected abdominally or given po) on male *Drosophila melanogaster* were studied by the sex-linked recessive-lethal test. Injection of NaN₃ at pH 4.6 or 3.8 had no significant effect on the frequency of recessive-lethal mutations in any of the male germ cell stages. A 24-hr feeding of 0.1 mM azide (pH 4.6) produced a nonsignificant increase in the frequency of sex-linked recessive-lethal mutations (0.98%) in brood B, which corresponded to spermatids. The overall mutation frequency in flies fed for 3 days on 0.1 mM azide (pH 4.6) was significantly higher than that among the controls and flies fed 5 mM azide (pH 7.0). Thus, even at low pH, NaN₃ is ineffective as a mutagen after injection into male *Drosophila*, but it is weakly mutagenic when fed for 3 days at a concentration of 0.1 mM at pH 4.6. (14 refs)

- 79-3180 Δ¹Tetrahydrocannabinol and 1α,2α-Epoxyhexahydrocannabinol: Mutagenicity Investigation in the Ames Test. (Eng) Glatt, H. (Section Biochemical Pharmacology, Inst. Pharmacology, Univ. Mainz, Obere Zahlbacher Strasse 67, D-6500 Mainz, W. Germany); Ohlsson, A.; Agurell, S.; Oesch, F. *Mutat Res* 66(4): 329-335; 1979.

Because many epoxides are mutagens, the mutagenicity of 1α,2α-epoxyhexahydrocannabinol (EHC) as well as that of Δ¹-tetrahydrocannabinol (THC) toward *Salmonella typhimurium* strains TA1535, TA1537, TA98, and TA100 was investigated in the presence and absence of an S9 mix from liver homogenates of Aroclor 1254-treated rats. Because EHC can be converted into a dihydrodiol by epoxide hydase, an epoxide hydratase inhibitor was added to the metabolizing system in some experiments. Although several other epoxides and additional positive controls, either not requiring activation or being activated under similar conditions, showed strong mutagenicity, there were no indications of a mutagenic hazard due to EHC or THC. (19 refs)

- 79-3181 Antioxidants Reduce the Mutagenic Effect of Malonaldehyde and β-Propiolactone. Part IX,

Antioxidants and Cancer. (Eng) Shamberger, R. J. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106); Corlett, C. L.; Beaman, K. D.; Kasten, B. L. *Mutat Res* 66(4): 349-355; 1979.

The ability of antioxidants (vitamin C, vitamin E, selenium, and butylated hydroxytoluene) to reduce the mutagenic effects of malonaldehyde (MA) and β -propiolactone (PL) was studied using *Salmonella typhimurium* strains hisG46 and TA1975, which mutate by base-pair substitution, and variants hisC207, his3076, TA1977, hisD3052, and TA1978, which are frameshift mutants. MA increased mutagenesis in TA1975, hisC207, hisC3076, hisD3052, and TA1978 in a non-dose-dependent fashion, but it had no effect on hisG46. PL increased mutagenesis in all strains. The antioxidants decreased MA-induced mutagenesis in hisC207, hisC3076, TA1978, and, to some extent, in hisD3052, but not in hisG46 or TA1975. PL-induced mutagenesis was reduced by the antioxidants in all strains. (15 refs)

79-3183 Mutagenic Action of a Series of Epoxides. (Eng) Wade, M. J. (Life Sciences Res. Office, Federation American Societies Experimental Biology, 9650 Rockville Pike, Bethesda, MD 20014); Moyer, J. W.; Hine, C. H. *Mutat Res* 66(4): 367-371; 1979.

The mutagenicity of 13 epoxide compounds was determined in a bacterial plate assay system using the histidine-dependent *Salmonella typhimurium* tester strains TA98 (for frameshift mutagens) and TA100 (for base-pair substitution mutagens). Mutagenicity was evaluated both with and without the addition of a rat liver microsomal extract. Dieldrin, the diglycidyl ether of bisphenol A, and three of its homologs were not mutagenic. Allyl glycidyl ether, n-butyl glycidyl ether, vinyl cyclohexene diepoxide, glycidol, glycidaldehyde, diglycidyl ether, diepoxybutane, and the diglycidyl ether of substituted glycerine were mutagenic to TA100, causing reversion of the bacteria to histidine independence. Dose-response curves of the mutagenicity of the latter four compounds were obtained. On a molar basis, glycidaldehyde was about 20-50 times more potent in producing mutation than the other three epoxides. In general, the mutagenicity of the epoxides was not enhanced or diminished by the addition of the microsomal extract. (9 refs)

79-3193 Decrease in Collagen Production in Normal and Rous Sarcoma Virus-transformed Chick Embryo Fibroblasts Induced by Phorbol Myristate Acetate. (Eng) Delclos, K. B. (Dept. Pharmacology, Harvard Medical Sch., Boston, MA 02115); Blumberg, P. M. *Cancer Res* 39(5): 1667-1672; 1979.

The ability of the potent tumor promoter phorbol-12-myristate 13-acetate (PMA) to inhibit collagen synthesis was investigated in chick embryo fibroblasts (CEF). Collagen synthesis, as measured by the rate of formation of [³H]hydroxyproline from [³H]proline, was decreased in cells treated with PMA (33 or 200 nanograms/ml) but not in cells treated with the parent alcohol phorbol (1 µg/ml). The effect was max at 33 nanograms/ml. The decrease in collagenase-sensitive proteins was confirmed by polyacrylamide gel electrophoresis of cell lysates, indicating that the decrease could not be ascribed simply to an effect on prolyl hydroxylase. Although a decrease in collagen synthesis was observed after 1 day, 5 days were required for a max reduction to 20% of that of dimethyl sulfoxide-treated controls. The effect of PMA on collagen synthesis was reversible. It was, therefore, not the result of a permanent transformation of the cells or of the selection of a cell population with a reduced capacity for collagen synthesis. Collagen synthesis was decreased in CEF transformed by Rous sarcoma virus. Treatment of these cells with PMA for 5 days brought about a further decrease to 50% of the level in dimethyl sulfoxide-treated transformed controls. (38 refs)

79-3200 Tumor Promoter-induced Adhesion of the DS19 Clone of Murine Erythroleukemia Cells. (Eng) Yamasaki, H. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, 150 Cours Albert Thomas, Lyon 69372, France); Weinstein, I. B.; Fibach, E.; Rifkind, R. A.; Marks, P. A. *Cancer Res* 39(6, part 1): 1989-1994; 1979.

When suspension cultures of certain 12-O-tetradecanoylphorbol-13-acetate (TPA)-sensitive clones of murine erythroleukemia cells (MELC) are exposed to TPA, they become adherent to the tissue culture plate but TPA-resistant clones do not. The results of further studies of this phenomenon are presented. The TPA-induced adhesion of the DS19 clone of MELC to the surface of tissue culture flasks was apparent within 20 min and was max within 45

min. The effect required as little as 1-5 nanograms/ml TPA, and it was temperature-dependent. Adhesion was not inhibited by actinomycin D or cycloheximide, but partial inhibition was observed with colchicine and cytochalasin B. Among six phorbol esters and other plant diterpenes tested, there was good correlation between effectiveness in inducing MELC adhesion and mouse skin tumor-promoting activity. TPA-induced adhesion was not seen when MELC were grown in bacterial flasks, yet differentiation was inhibited under these conditions, indicating that adhesion is not a prerequisite for TPA inhibition of differentiation. Two subclones of DS19 that are resistant to TPA-induced inhibition of differentiation showed no adhesion to tissue culture flasks in the presence of TPA or other phorbol ester tumor promoters. When TPA-sensitive and -resistant cells were cocultured and TPA was added, almost all of the TPA-sensitive cells became adhesive to the plate, yet very few of the TPA-resistant cells became adhesive. These results suggest that an early site of action of TPA in MELC is the cell-surface membrane. The changes in MELC adhesion induced by TPA may provide clues to its mechanism of action and provide a rapid in vitro assay for certain types of tumor promoters. (35 refs)

79-3206 Increased Cyclic Adenosine 3':5'-Monophosphate Phosphodiesterase Activity in the Epidermis of Phorbol Ester-treated Mouse Skin and in Papillomas. (Eng) Mufson, R. A. (Inst. Cancer Res. Columbia Univ. Coll. Physicians and Surgeons, 701 W. 168 St., New York, NY 10032); Simsiman, R. C.; Boutwell, R. L. *Cancer Res* 39(6, part 1): 2036-2040; 1979.

The relationship of the phorbol ester-mediated induction of cyclic AMP phosphodiesterase activity to tumor promotion was examined. The potent tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) produced a two- to threefold increase in the activity of both the low- and high-affinity forms of cyclic AMP monophosphate phosphodiesterase activity 13 hr after application to female CD-1 mouse skin [17 nanomoles (nmol) in acetone]. At 13 hr after application, enzyme induction was dependent on the TPA dose applied (0.17-17 nmol). The magnitude of the enzyme induction correlated with the tumor-promoting activity of TPA and other phorbol esters: TPA > phorbol-12,13-didecanoate > phorbol-12,13-dibenzoate. The induction of the low-affinity phosphodiesterase could be blocked by prior injection of the microtubule poisons colchicine and vinblastine (250 nmol ip 3 hr before TPA). The low-affinity cyclic AMP phosphodiesterase activity of the epidermal component of mouse skin papillomas produced by two-stage tumorigenesis was three times that of the surrounding uninvolved epidermis. 79-3210 Studies on the Esophagus. II. Enhancement of [³H]Thymidine Incorporation in Rat Esophagus by *Bidens pilosa* (A Plant Eaten in South Africa) and by Croton Oil. (Eng) Mirvish, S. S. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE 68105); Rose, E. F.; Sutherland, D. M. *Cancer Lett* 6 (3): 159-165; 1979.

The effects of *Bidens pilosa* (a plant eaten in South Africa) and croton oil in the diet on ³H-thymidine incorporation (TI) into DNA was studied in rat esophagus epithelium. The test materials were fed with a semisynthetic diet for 1 or 2 wk, and TI were measured 1 hr after ip injection of ³H-thymidine. TI was enhanced up to 2.3-fold in the esophagus of rats fed dried *B. pilosa* leaves (1:4 mixture of leaves:diet). A smaller enhancement of TI occurred with an ethanol extract of *B. pilosa* leaves, with a methanol-water fraction of the extract, and when *B. pilosa* was boiled under conditions resembling those used in cooking. The enhancement was not as great as that with unboiled material, indicating that some, but not all, of the active material survived the boiling. No enhancement occurred with raw spinach. TI was also enhanced significantly (1.08- to 1.21-fold) when croton oil was administered in the diet at levels of 2-6 g/kg. Since tumor promoters usually cause cell proliferation, these results suggest that *B. pilosa* consumption might be a promoting factor in the etiology of esophageal cancer in parts of South Africa that have a high incidence of this cancer. (17 refs)

79-3211 Effect of *Salmonella enteritidis* 11RX Infection on Two-Stage Skin Carcinogenesis in Mice. (Eng) Ashman, L. K. (Dept. Microbiology and Immunology, Univ. Adelaide, Adelaide 5000, South Australia, Australia); Kotlarski, I. *Aust J Exp Biol Med Sci* 56(6): 695-701; 1978.

The effects of *Salmonella enteritidis* 11RX infection on tumorigenesis in mice initiated with topical 7,12-dimethylbenz(a)anthracene (DMBA: 100 µg in 0.2 ml acetone) and promoted with repeated applications of croton oil (0.2 ml of 0.5% soln in acetone, 2x/wk 3-5 wk after initiation) were examined. DMBA/croton oil treatment produced small papillomas that gradually developed into lesions ranging from squamous papillomas to keratocanthomas and early invasive squamous cell carcinomas. Iv inoculation of LACA and (BALB/c x C57Bl/6J)F₁ mice with 10⁵ live 11RX 1 wk before DMBA application had no protective effect on tumorigenesis. However, a significant but transient protective effect was

achieved when mice were immunized with 11RX 4 wk before DMBA treatment and at intervals before and during promotion with croton oil. Relative to the LACA mice, (BALB/c x C57Bl/6J)F₁, BALB/c, C57Bl/6J, and CBA mice were more resistant to DMBA/croton oil skin carcinogenesis. (12 refs)

79-3219 Ultrastructural Features of Glioma Formation in Rats. (Rus) Abdullakhodzhaeva, M. S. (Dept. Pathoanatomy, Medical Inst., Tashent, USSR); Ibragimov, T. K. *Biull Eksp Biol Med* 87(4): 371-375; 1979.

9,10-Dimethyl-1,2-benz(a)anthracene (DMBA) pellets were implanted intracerebrally in rats, and changes that occurred in the astrocytes during glioma formation were studied ultrastructurally. In one group of rats, the DMBA pellet was implanted 45 days after the animals underwent pinealectomy. Brain specimens were obtained on days 1, 5, 15, 30, 45, 60, 90, 120 and 150 postimplantation (PI). On PI days 15-30, the pinealectomized rats showed a predominance of astrocytes with an oval nucleus, an enlarged perinuclear space, and a granular endoplasmic reticulum (collectively termed intracellular hyperplasia). By PI day 45, however, the number of these astrocytes was reduced, and between days 60 and 90, astrocytes with an osmiophobic cytoplasm predominated. Rats subjected to intracerebral implantation of DMBA alone showed only intracellular hyperplasia on PI days 15-30. These findings indicate that pinealectomy potentiates the malignant transformation of glial cells. (15 refs)

79-3223 Effect of Thymosin and Adrenalectomy on Development of Chemically Induced Tumors. (Ukr) Chebotarev, V. F. (Res. Inst. Endocrinology and Metabolism, Kiev, USSR); Grinevich, Iu. A. *Dopov Akad Nauk Ukr RSR [B]* (12): 1121-1123; 1978.

An attempt was made to determine whether thymosin (TM) can enhance the immunocompetence of adrenalectomized animals against the development of chemically induced tumors. Random-bred rats were injected with 7,12-dimethylbenz(a)anthracene (DMBA: 3 doses of 2 mg, iv, at 3-day intervals). Ten days after the termination of DMBA administration, the rats were adrenalectomized and/or given injections of TM (10 mg, iv, at 10-day intervals for 3 mo). Adrenalectomy + TM significantly decreased the number of animals with mammary gland tumors. The max difference was recorded 22 wk after the termination of DMBA administration, when tumors were detected in 78.8% of the animals exposed to DMBA alone (controls), 58.3% of the animals DMBA + adrenalectomy, 51.7% of the rats treated with DMBA + TM, and 25.0% of the rats treated with DMBA + adrenalectomy + TM. - The carcinogenic and hyperplastic effects of dihydrodiols derived from 7-methylbenz(a)anthracene (MBA) or benzo(a)pyrene (BP) were tested by topical application to female CDI mice and female Wistar rats. The 3,4-dihydrodiol derived from MBA was more effective in producing skin tumors in mice than MBA, and MBA was more effective in this respect than the related 1,2-, 5,6-, and 8,9-dihydrodiols. The 7,8-dihydrodiol of BP was less effective than BP in the induction of hyperplasia and the suppression of sebaceous glands in mouse skin. The 7,8-dihydrodiol was also very much less active than BP in the induction of sarcomas in rats. The data indicate that the 7,8-dihydrodiol of BP may be more effective as an initiating agent than as a complete carcinogen. Of the systems tested, only the mouse skin initiation-promotion model gave results that are in broad agreement with data that have identified the 7,8-dihydrodiol of BP and the 3,4-dihydrodiol of MBA as important in the metabolic activation of the carcinogenic parent hydrocarbons. Box Y, Oak Ridge, TN 37830); Gleason, G. L.; DiGiovanni, J.; Sukumaran, K. B.; Harvey, R. G. *Cancer Res* 39(6, part 1): 1934-1936; 1979.
- The abilities of the racemic *trans*-3,4-, 5,6-, and 8,9-dihydrodiols of 7,12-dimethylbenz(a)anthracene (DMBA) to initiate skin tumors in mice were determined with the use of a two-stage system of tumorigenesis. Groups of 30 female Sencar mice received a single topical application of the test compound, followed 1 wk later by twice-weekly applications of 2 μ g 12-O-tetradecanoylphorbol-13-acetate.

CHEMICAL CARCINOGENESIS

The incidence of papillomas was recorded weekly, and they were removed at random for histological verification. DMBA and DMBA dihydrodiols were applied topically at a dose of either 10 or 100 nanomoles in acetone. The 7,12-dimethylbenz(a)anthracene trans-3,4-dihydrodiol was much more active as a tumor initiator than the parent hydrocarbon, producing 15.20 and 22.84 tumors/mouse at 15 wk at the two respective doses, vs 4.80 and 10.20 tumors/mouse produced by DMBA. The trans-5,6- and 8,9-dihydrodiols were essentially inactive as skin tumor initiators. The results suggest that the 3,4-dihydrodiol of DMBA is a proximal carcinogen and that the bay region diol-epoxide may be the ultimate carcinogenic form of DMBA. (42 refs)

Several in vitro phenotypic characteristics frequently associated with neoplastic cells were examined in a series of spontaneously transformed and benzo(a)pyrene (BP)-transformed Syrian hamster clonal cell lines that differed in their degree of tumorigenicity. Some chemically transformed cell lines were highly tumorigenic in nonimmunosuppressed newborn hamsters, requiring ≤ 10 cells to produce tumors, others required 10^4 - 10^5 cells. Of five spontaneously established cell lines studied, only one became tumorigenic. After 34 in vitro passages, it was capable of producing tumors following inoculation of newborn hamsters with 2×10^6 cells. Anchorage-independent cloning efficiency, elevated fibrinolytic activity, reduced serum requirement for growth, increased cloning efficiency, and loss of intracellular actin organization were correlated with tumorigenicity, both qualitatively and quantitatively, by nonparametric statistical analyses. These results suggest that the factors controlling tumorigenicity in this test system are the growth properties of the cells rather than their antigenicity in the host. (44 refs)

The distribution of covalently bound ^3H -benzo(a)pyrene (^3H -BP) was investigated in subfractions of rat lung and liver nuclei in vivo and in vitro. For the in vivo experiments, 75 μCi ^3H -BP was injected sc into 2- to 3-wk-old rats, and the animals were killed 2.5 hr later. For in vitro labeling, rat lung tissue was incubated with medium containing 75 μCi ^3H -BP for 90 min. Lung and liver nuclei were fractionated into a matrix and a chromatin fraction. Both in vivo and in vitro, the DNA, RNA, and protein of the matrix fraction were labeled more extensively (3- to 10-fold) than the DNA, RNA, and protein of the chromatin fraction. The specific radioactivity of protein was highest and that of DNA lowest. In vivo, the rates of ^3H -BP incorporation were higher into liver RNA and DNA than into lung RNA and DNA. It is suggested that BP molecules, which are activated at the nuclear envelope by the benzo(a)pyrene hydroxylase system, may react preferentially with nearby targets, such as the nuclear matrix. The metabolism of benzo(a)pyrene (BP) to oxidative (primarily ethyl acetate-soluble) and conjugated (primarily water-soluble) metabolites in cells from Fischer 344 rat tracheas at different levels of tissue and cell organization was studied. Primary cultures from tracheal explants and a

nontumorigenic tracheal epithelial cell line (2Cl), derived from 12-O-tetradecanoylphorbol-13-acetate-exposed tracheal explants, metabolized BP to qualitatively similar organic solvent-soluble and water-soluble metabolites. Similar metabolites were formed by short-term organ cultures of tracheas. In contrast, a tumorigenic tracheal epithelial cell line (1000 W) did not metabolize BP to any significant extent. The major metabolites formed by these different tracheal systems were 9,10-dihydro-9,10-dihydroxybenzo(a)pyrene with smaller amounts, mainly as their glucuronide conjugates, of 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene, 3-hydroxybenzo(a)pyrene, and 9-hydroxybenzo(a)pyrene. The higher formation of dihydrodiols, precursors of highly reactive diol-epoxides, relative to monohydroxybenzo(a)pyrenes, together with low rates of detoxification of the dihydrodiols by conjugation, may in part explain the high susceptibility of the trachea to carcinogenesis. This study indicates that nontumorigenic respiratory epithelium at different levels of organization possesses similar activating and detoxifying enzymes. Since it is the balance of these oxidative and conjugating enzymes that determines how much of a metabolite is available for reaction with critical cellular macromolecules, these enzymes appear to be suitable for metabolic studies of factors affecting initiation and transformation of respiratory tract epithelium. (33 refs)

79-3250 Isolation of Stable Mutagenic Photodecomposition Products of Benzo(a)pyrene by Thin-Layer Chromatography. (Eng) Issaq, H. J. (Chemical Carcinogenesis Program, NCI, Frederick Cancer Res. Center, Frederick, MD 21701); Andrews, A. W.; Janini, G. M.; Barr, E. W. *J Liquid Chromatography* 2(3): 319-325; 1979.

The effects of UV radiation on the stability of benzo(a)pyrene (BP) in soln and on thin-layer chromatography (TLC) plates were examined, and stable photodecomposition products were isolated and tested for mutagenic activity. When BP solns were spotted on silica gel, alumina, cellulose, and reversed-phase TLC plates and dried under nitrogen, followed by development and elution, no loss to decomposition was observed. When the solns were spotted on the plates and allowed to dry in a stream of air, several developed spots were observed. Similar results were obtained when plates spotted with BP were exposed to sunlight. Two of these products were eluted off the plate and were characterized as the 1,6- and 3,6-BP quinones. Solns of BP (334 $\mu\text{g}/\text{ml}$) were streaked on silica gel plates, allowed to dry, exposed to sunlight or UV radiation for 1 hr, and then developed. Regions from the developed plates were eluted and tested for mutagenicity. BP was mutagenic for the base-pair-substitution *Salmonella typhimurium* strain TA100 and the frameshift TA1538, with and without metabolic activation. These data suggest that the photodecomposition products may be more highly mutagenic than the parent compound. The two identified

CHEMICAL CARCINOGENESIS

photodecomposition products do not account for the high mutagenicity observed. Thus, characterization of the stable photodecomposition products of polycyclic aromatic hydrocarbons on coated TLC plates may lead to the identification of previously unappreciated environmental carcinogens. (16 refs)

79-3251 Differences in Benzo(a)pyrene-4,5-epoxide Hydrase Activities of Intact Hamster Hepatocytes, Embryo Cells, and Homogenates of These Cells (Meeting Abstract). (Eng) Raineri, R. 79-3252 Metabolism and Excretion of Benzo(a)pyrene 4,5-Oxide by the Isolated Perfused Rat Liver. (Eng) Smith, B. R. (Lab. Pharmacology, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Triangle Research Park, NC 27709); Bend, J. R. *Cancer Res* 39(6, part 1): 2051-2056; 1979.

Benzo(a)pyrene 4,5-oxide was metabolized in isolated perfused Sprague-Dawley rat liver by epoxide hydrase and glutathione S-transferases to the corresponding dihydrodiol and to thioether conjugates (derivates of glutathione), respectively. Epoxide hydrase was more important relative to the glutathione S-transferases in the biotransformation of this oxide by the intact organ than was indicated by the results of earlier studies with subcellular fractions. The dihydrodiol was rapidly released into the circulation or conjugated with glucuronic acid; sulfuric acid esters were not found. All conjugated metabolites were excreted rapidly in the bile, but they were also released into the circulation. The enzymatic systems responsible for the metabolism and excretion of benzo(a)pyrene 4,5-oxide remained viable in the perfused liver for at least 60 min. The toxicological significance of the release of polycyclic aromatic hydrocarbon metabolites from the liver into the vascular circulation and the possible significance of uridine diphosphate:glucuronyltransferase activity in preventing chemically induced carcinogenesis are discussed. 79-3265 Mutagenicity of 43 Structurally Related Heterocyclic Compounds and Its Relationship to Their Carcinogenicity. (Eng) Glatt, H. R. (Section Biochemical Pharmacology, Inst. Pharmacology, Univ. Mainz, Obere Zahlbacher Strasse 67, D-6500 Mainz, W. Germany); Schwind, H.; Zajdela, F.; Croisy, A.; Jacquignon, P. C.; Oesch, F. *Mutat Res* 66(4): 307-328; 1979.

The mutagenicity and carcinogenicity of 43 structurally related heteropolycyclic compounds were evaluated, and the results were compared. Mutagenicity was determined in the Ames assay with *Salmonella typhimurium* strains TA1535, TA1537, TA98 and TA100 in the presence and absence of a liver 10,000-g supernatant from rats treated with Aroclor 1254. Carcinogenicity was tested by sc injection

of the compounds into XVIIInc/Z mice. Eighteen test compounds showed carcinogenic activity, some strongly, others only weakly. Of these, 17 were also mutagenic: 1 weak carcinogen did not revert the *Salmonella* strains. There was no quantitative correlation between degree of mutagenicity and carcinogenicity. Of the 25 substances that did not produce tumors, 13 showed mutagenicity (12 in the presence, 2 in the absence of the liver homogenate). The mutagenic effects of these compounds were quantitatively similar to those of the compounds that produced tumors. The most sensitive strain of *S. typhimurium* was TA100, detecting all 30 mutagens. TA98 was mutated by 25 compounds, TA1537 by 16 compounds. No mutagenic effects were seen with TA1535. Possible reasons for the high percentage of apparently false-positives in the Ames assay and the lack of a quantitative correlation between mutagenic and carcinogenic potency are given. The complexity of the metabolism of these heterocyclic compounds may lead to critical differences in metabolism in mouse sc tissue in vivo and in liver homogenates from Aroclor-treated rats. - The relationship between the effects of the inducers phenobarbital (PB) and 3-methylcholanthrene (MC) on hamster liver microsomal mixed-function-oxidase activities and the abilities of the microsomes to activate known carcinogens was studied. Both inducers increased the amount of cytochrome P-450 in the microsomes, aminopyrine demethylase activity, and biphenyl 4-hydroxylase activity when given for 8 days. The ability of liver homogenates from treated animals to activate compounds to mutagens was tested using the Salmonella/microsome test. Neither inducer appreciably altered the mutagenicity of 2-acetylaminofluorene, ben-zidine, benzo(a)pyrene, aflatoxin B₁, or sterigmatocystin. The mutagenicity of MC was increased when homogenates from MC-treated hamsters were used as a source of activating enzymes, and this mutagenicity could be correlated with increased biphenyl 2-hydroxylase activity. - 79-3281** Mutagenicity of Phenanthrene and Phenanthrene K-Region Derivatives. (Eng) Bucker, M. (Section Biochemical Pharmacology, Inst. Pharmacology, Univ. Mainz, Obere Zahlbacher Strasse 67, D-

6500 Mainz, W. Germany); Glatt, H. R.; Platt, K. L.; Avnir, D.; Ittah, Y.; Blum, J.; Oesch, F. *Mutat Res* 66(4): 337-348; 1979.

Phenanthrene (PAT) and nine of its K-region derivatives were tested for mutagenicity in the *Salmonella typhimurium* reversion assay using the histidine-dependent strains TA1535, TA1537, TA1538, TA98, and TA100 and in the rec assay using *Bacillus subtilis* strains H17 (rec+) and M45 (rec-). In the reversion assay, the strongest mutagenic effects were observed with phenanthrene 9,10-oxide (I), 9-hydroxyphenanthrene (II), and N-benzylphenanthrene 9,10-imine (III). Interestingly, the mutagenic potency of the arene imine was similar to that of the corresponding arene oxide. The mutagenic effects of these derivatives were much weaker than that of the positive control, benzo(a)pyrene 4,5-oxide (IV). Even weaker mutagenicity was found with cis- (V) and trans-9,10-dihydroxy-9,10-dihydrophenanthrene (VI). The other derivatives were inactive in this test. However, 9,10-dihydroxyphenanthrene and 9,10-phenanthrenequinone were more toxic to *B. subtilis* strain M45 strain than to H17. This was also true for compounds I and II, but not with the other test compounds that reverted (compounds III-VI) or did not revert (PAT, 9,10-bis-(p-chlorophenyl)phenanthrene 9,10-oxide, 9,10-diacetoxyphenanthrene) the *Salmonella* tester strains. Although the K region is a main site of metabolism and although all potential K-region metabolites were mutagenic, PAT did not show a mutagenic effect in the presence of mouse liver microsomes and an NADPH-generating system under standard conditions. However, when epoxide hydratase was inhibited, PAT was activated to a mutagen that reverted *his*- *S. typhimurium*. Thus, demonstration of the mutagenicity of metabolites plus the knowledge that a major metabolic route proceeds via these metabolites do not automatically imply a mutagenic hazard of the parent compound, because the metabolites in question may not accumulate in sufficient quantities and, therefore, the presence and relative activities of enzymes that control the mutagenically active metabolites are crucial. 79-3287 Electrophilic Superdelocalizability and Carcinogenesis by Polycyclic Aromatic Hydrocarbons--Pullman Theory. (Eng) Memory, J. D. (Sch. Physical and Mathematical Sciences, North Carolina State Univ., Raleigh, NC 27606). *Int J Quantum Chem* 15(4): 363-368; 1979.

Correlations between electrophilic superdelocalizabilities in the K region and carcinogenic potency were studied for benzantracene, 5,6- and 7,8-benzacridine, chrysene, and benzphenanthrene and their monomethyl and dimethyl derivatives. The results support the Pullman hypothesis that carcinogenicity is correlated with a reaction K region and an inactive L region. If the basic hypothesis is correct, the first step of the chain of reactions leading to carcinogenesis would be electrophilic attack of a carcinogenic hydrocarbon in the K region. The fact that several non-carcinogens have active K region as well as active L regions supports the L-region portion of the Pullman hypothesis. (10 refs)

79-3288 Ozonation of Mutagenic and Carcinogenic Polyaromatic Amines and Polyaromatic Hydrocarbons in Water. (Eng) Burleson, G. R. (Lobund Lab., Dept. Microbiology, Univ. Notre Dame, Notre Dame, IN 46556); Caulfield, M. J.; Pollard, M. *Cancer Res* 39(6, part 1): 2149-2154; 1979.

The *Salmonella*-microsome assay was used to monitor the

CHEMICAL CARCINOGENESIS

effects of ozone on the mutagenicity of selected carcinogens and mutagens in water. Short periods of ozonation (1-4 min) completely inactivated the mutagenicity of several polyaromatic amine mutagens, including acriflavine, proflavine, and β -naphthylamine. Selected polyaromatic hydrocarbons were also sensitive to ozonation. Kinetic studies revealed that the mutagenicity of benzo(a)pyrene, 3-methylcholanthrene (3-MC), and 7-12-dimethylbenz(a)anthracene (DMBA) was destroyed after short periods of ozonation. To correlate loss of mutagenicity with loss of carcinogenicity, two polyaromatic hydrocarbons were treated with ozone, extracted from water with hexane, and tested for carcinogenicity in mice. When DMBA and 3-MC were treated with ozone, there was a substantial reduction in carcinogenicity compared with that in control groups exposed to hexane extracts of oxygenated DMBA and 3-MC. However, a small number of tumors developed in the group of animals receiving a hexane extract of ozonated DMBA. This activity may be due to breakdown products of DMBA that are not mutagenic to the Salmonella tester strains used. (32 refs)

Syrian golden hamster fetal cells mixed with irradiated hamster fetal cells were used in several studies of the phenomenon of transformation. Agents that are potent carcinogens in vivo proved to be potent transforming agents in vitro, but they reduced the cloning efficiency. Dose-response experiments showed that transformation is independent of toxicity and that it appears to be a one-hit

phenomenon that results from induction rather than selection. Agents (ie, α -naphthoflavone) that protect cells from the lethality induced by benzo(a)pyrene (BP) can either inhibit or promote BP transformation. The transforming ability of various agents may be increased by metabolic activation in vivo, the transformation in such cases being unassociated with viral activation. Transformed cells are able to produce tumors in vivo, and transformation and the subsequent neoplasia usually are not associated with an observable specific karyotypic abnormality. Pretreatment of cells with x-irradiation or methyl methanesulfonate or posttreatment with caffeine increases the frequency of chemical transformation. Most, if not all, chemical carcinogens will increase the sensitivity of hamster fetal cells to transformation by the carcinogenic simian adenovirus SA7. The enhancement of virus transformation is related to the length of chemical treatment and the interval between chemical and viral addition. Some of the transforming agents may also show mutagenic activity and produce chromosome aberrations in some systems. However, although DNA is the critical site for a mutagen, the critical target(s) of chemical carcinogens is still unknown. (49 refs)

79-3293 Membrane Transformation in Malignancy: The Normal and Neoplastic Transitional Epithelium of the Rat Urinary Bladder. A Thin Section and Freeze-Fracture Study. (Eng) Thiele, J. (Inst. Pathology, Medical Sch. Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany); Adolphs, H. D.; Reale, E. *J Submicrosc Cytol* 11(2): 249-261; 1979.

Thin sections and freeze-fracture replicas of normal Wistar rat transitional epithelium and of an N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT)-induced infiltrating papillary carcinoma of the urinary bladder in these rats were examined electron microscopically to study possible alterations of the plasma membranes following malignant transformation. Thin sections of the carcinoma showed that most of the cells exhibited numerous microvilli and a broad glycocalyx at their luminal surface; the high degree of asymmetry of the luminal aspect of the plasma membrane had disappeared. In addition, the characteristic discoid vesicles of the normal urothelium were replaced by flattened vesicles containing electron-dense material. Replicas of freeze-fractured normal transitional cells demonstrated plaques of closely arranged particles within the luminal plasma membrane and the limiting membrane of the discoid vesicles. Similar par-

ticulated plaques also marked the membrane of some sacculi of the Golgi apparatus. Replicas of freeze-fractured papillary carcinoma cells revealed the disappearance of the particulated plaques from the membranes in all these sites, an alteration that coincided with the loss of membrane asymmetry in thin sections. S-Adenosylmethionine synthetase (SAMS) isozymes were studied in hepatic nodules, primary hepatocellular carcinomas (HCC's), and various transplantable HCC's induced in rats by dietary acetylaminofluorene. With the exception of hepatoma 7800, the intermediate-Km isozyme was the only enzyme species detectable in transplantable hepatomas, including 7777, 311c, 253, 252, 56, and Novikoff hepatoma. Although hepatoma 7800 retained all of the hepatic isozymes, the levels of various isozymes were different from those of normal liver. During acetylaminofluorene hepatocarcinogenesis, there was an alteration in enzyme composition that commenced in neoplastic nodules and eventually attained the pattern commonly observed for many primary and transplantable HCC's. Evidence that the intermediate-Km isozyme of the Novikoff hepatoma was derived from the low-Km isozyme and that protein factors were partly responsible for this higher Km is presented. This alteration of the kinetic properties of tumor isozyme was unique to neoplastic nodules and tumors and, therefore, may be a significant characteristic of malignant evolution. The existence of an SAMS-transfer RNA (tRNA) methyltransferase complex was supported by the demonstration of cochromatography of these two enzymes on Sepharose 6B, coprecipitation at pH 5, and a higher efficiency of utilization of SAMS-synthesized S-adenosylmethionine by tRNA methyltransferases in the enzyme complex than that provided exogenously. After pH 5 treatment, most of the tumor enzyme complex retained the complex form, whereas liver enzyme complex was almost totally dissociated, indicating that tumor enzyme complex was more stable than liver enzyme complex against pH variations. The difference in the stability of this enzyme complex is probably due to factors characteristically associated only with SAMS from neoplastic tissues. (42 refs)

The effects of ascorbic acid on the covalent binding of ¹⁴C-labeled N-hydroxy-2-acetylaminofluorene (NOH-2AAF) to DNA were studied to investigate the apparent inverse relationship between mutagenicity and protein covalent binding in this system. NOH-2AAF became covalently bound to DNA during generation of the reactive N-sulfate ester. Elution of DNA digests from Sephadex LH-20 columns yielded two peaks of radioactivity (fractions A and B). The presence of these fractions was dependent on the sulfation reaction, since nonincubated zero-time samples had very little radioactivity associated with them. The radioactivity in fraction B appeared only when DNA was present during sulfation and during generation of the arylating species. This fraction may represent a 2AAF guanosine monophosphate adduct. The amount of radioactivity in fraction A was almost the same whether or not DNA was present during the reaction. Fraction A probably represents NOH-2AAF covalently bound to protein that associates with DNA and is not lost during DNA purification. Ascorbic acid inhibited total binding by 78% and DNA binding by 88%, as measured in fraction B. Since previous reports demonstrated that ascorbic acid increases mutagenesis 12-fold under these conditions, it is suggested that free radicals may play a role in the non-covalent ascorbate-dependent increase in mutagenesis. 79-3328 Dietary Fibre and Experimental Colon Cancer in the Rat. (Eng) Asp, N. G. (Dept. Nutrition, Chemical Center, Univ. Lund, Box 740, S-220 07, Lund 7, Sweden); Bauer, H.; Dahlqvist, A.; Fredlund, P.; Oste, R. *Nutr Cancer* 1(2): 70-73; 1979.

The possible effect of three different types of dietary fiber, wheat bran, carrot fiber, and citrus pectin, on tumor development was investigated in male Sprague-Dawley rats. The rats were fed a basic diet with or without wheat bran (4:1), carrot fiber (4:1), or citrus pectin (13.8:1) from 3 days before to 14 days after the administration of 1,2-dimethylhydrazine (DMH: 15 mg/kg sc, 1x/wk for 12 wk). The animals were killed 12-14 wk after the last DMH injection. The number of rats with colorectal tumors was as follows: 35/40 rats on the basic diet, 36/40 given wheat bran, 36/40 given carrot fiber, and 39/40 given citrus pectin. In addition, each group had about 20 infiltrating adenocarcinomas in the small intestine and several ear duct tumors. No tumors were detected in any other organs. The rats fed the wheat bran diet had more than twice the amount of fecal dry substance than the rats fed the basic diet, but no protective effect of wheat bran against the development of colorectal tumors was evident. The reason for the enhancement of carcinogenesis seen with the citrus pectin is not known. (17 refs)

79-3329 Effect of 2-Nitrofluorene, 1,2-Dimethylhydrazine, and Azoxymethane on *Salmonella typhimurium* Mutants in the Gastrointestinal Tract of Gnotobiotic Rats. (Eng) Carter, J. H. (Dept. Pharmacology, Harvard Medical Sch., Beth Israel Hosp., Boston, MA 02215); McLafferty, M. A.; Goldman, P. *Cancer Res* 39(6, part 1): 2026-2030; 1979.

The effect of *Lactobacillus plantarum* and *Bacteroides vulgatus* on the response of *Salmonella typhimurium* strain TA1538-associated gnotobiotic Sprague-Dawley rats to 2-nitrofluorene (NF) was investigated. Studies were also made of the use of other *Salmonella* tester strains in this

host-mediated assay to detect mutagenicity with the colon carcinogens 1,2-dimethylhydrazine (DMH) and azoxymethane (AM). After the ingestion of 3.4 mg NF in the diet, the fecal concentration of *his*⁺ revertants was greatly elevated in all groups of rats except those associated with TA1538 and *B. vulgatus*. The concentrations of the various bacteria were measured at eight sites in the gastrointestinal tract. *B. vulgatus* achieved high concentrations in the stomach when it was associated with TA1538, but its concentration was not as high when it was associated with *L. plantarum* plus TA1538. The concentration of *B. vulgatus* in individual rats correlated negatively with their response to NF. *B. vulgatus* readily reduced NF to 2-aminofluorene, a reaction that was negligible in cultures of *L. plantarum* and TA1538. Since 2-aminofluorene is less mutagenic than NF, *B. vulgatus* appears to diminish the revertant response by removing the more potent mutagen from within the gastrointestinal tract. Other Ames *Salmonella* tester strains (TA1535, TA100, and TA98) could also be maintained in association with otherwise germ-free rats. The feces of animals associated with TA1535 and TA100, however, showed a variable increase in the concentration of *his*⁺ revertants in response to the ingestion of DMH (21 mg/kg) and AM (19 mg/kg). 79-3331 Discontinuities in Dose Response Curves from Toxicological Tests. (Eng) Anderson, R. L. (Procter and Gamble Co., Miami Valley Labs., Cincinnati, OH). *Household Pers Prod Ind* 16(3): 68-86; 1979.

Studies concerning dose-response curves for nitrilotriacetic acid (NTA) and demonstrating a clear threshold dose for the induction of carcinogenesis by this chemical are surveyed. A National Cancer Institute study demonstrated a relationship between high levels of NTA ingestion and an increased incidence of urinary tract cancer in rats. Other studies demonstrated that carcinogenic doses of both H₃NTA (1% in drinking water) and Na₃NTA (2%) resulted in the appearance of crystalluria in rats. The only crystalline material present in the urine was CaNaNTA. In males, changes in urinary Ca levels occurred only when the urinary NTA concentration was at least 100 micromoles/g which resulted from 0.75% NTA in the diet; once this threshold dose was exceeded, urinary Ca increased linearly with NTA dose, up to approx 200 micromoles/g. In males, but not females, the level of Na₃NTA that produced saturation of urinary Ca output was associated with increased urine volume, hematuria, and increased kidney/body wt

ratios. At all NTA doses, including zero, females excreted more urinary Ca than males eating the same diet. The ability of the females to excrete more Ca did not saturate, as was shown for males. In both sexes, H_3NTA ingestion was associated with more urinary Ca than Na_3NTA ingestion at levels that produced the same urinary load of NTA. These results suggest that urinary tract tumors are associated only with NTA doses that produce crystalluria. Thus, secondary physical damage, and not an effect produced by a tissue accumulation process, appears to cause these tumors. In addition, it seems unreasonable to conclude that any extrapolation of carcinogenesis incidence to possible exposure levels of NTA would lead to a rational assessment of risk to humans. (no refs)

- 79-3333 Transformation of Hamster Embryo Cells by Cholesterol- α -Epoxide and Lithocholic Acid. (Eng) Kelsey, M. I. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701); Pienta, R. J. *Cancer Lett* 6(3): 143-149; 1979.

Cholesterol and three of its derivatives, cholesterol- α -epoxide, sulfolithocholic acid, and lithocholic acid, were tested for their ability to transform hamster embryo cells. Of the two cholesterol, only cholesterol- α -epoxide was active in this system, with transformation occurring at total concentrations of 54-2,100 nanomoles (nmol) [the positive control, 3-methylcholanthrene, produced max transformation (0.35%-1.0%) at a total concentration of 360 nmol]. In tests with sulfolithocholic and lithocholic acids, only lithocholic acid was active. Max transformation (0.11%-0.13%) occurred at the lowest doses tested (1.2-1.8 nmol). These results are the first examples of in vitro cell transformation activity by cholesterol derivatives and metabolites that may be important in colon carcinogenesis. The results suggest that the hamster embryo cell transformation system may be useful for screening endogenously formed steroid metabolites for their potential carcinogenicity. (29 refs)

- 79-3334 Vaginal Adenocarcinoma in a Gravid with Prenatal DES Exposure. (Eng) Del Castillo, H. (Dept. Gynecology, Medical Center del Oro Hosp., Houston, TX); Rubio, P. A.; Farrell, E. M. *Int J Gynaecol Obstet* 16(4): 271-273; 1979.

A case report is presented of a 22-yr-old pregnant woman with vaginal carcinoma who had been exposed to diethylstilbestrol (DES) in utero. The appearance of the tumor (in the 4th month of pregnancy) was consistent with descriptions of vaginal adenocarcinoma, but not metastatic adenocarcinoma. Surgical excision of the lesion failed, but interstitial irradiation was successful. Six mo after treatment, the patient gave birth to a normal term infant by cesarean section. Two subsequent children were delivered by cesarean section after normal pregnancies. There has been no evidence of metastatic disease or recurrence in 11.5 yr of follow-up. Since adenocarcinoma of the cervix and vagina is asymptomatic during its early growth and since these carcinomas may develop soon after menarche, girls exposed to DES prenatally should begin screening examinations either after first menstruation or at 14 yr of age, if menstruation has not yet begun. The recent identification of elevated serum (cathepsin B1) activity in tumor patients suggests the potential development of a serum enzyme test to detect recurrent disease. (4 refs)

- 79-3337 The Testicular Estrogen Receptor System in Two Strains of Mice Differing in Susceptibility to Estrogen-induced Leydig Cell Tumors. (Eng) Sato, B. (Third Dept. Internal Medicine, Osaka Univ. Hosp., Fukushima-ku, Osaka, Japan); Spomer, W.; Huseby, R. A.; Samuels, L. T. *Endocrinology* 104(3): 822-831; 1979.

Studies were conducted to establish the presence of an intracellular estrogen transport system in the Leydig cells of mouse testes and to compare the system in tumor-susceptible (BALB/c) and tumor-resistant [C_3H Bi (Z)] mouse strains. Cytosols obtained from cryptorchid testes of both mouse strains bound 17β -estradiol (E_2) and diethylstilbestrol (DES) specifically. The dissociation constant of this binding component for E_2 was 5×10^{-9} M. Gel filtration of the cytosol before incubation markedly increased the affinity (3×10^{-10} M). In vitro translocation of the cytosol binding component to the nucleus was demonstrated in both mouse strains using either estrogen.

CHEMICAL CARCINOGENESIS

Quantitation of the *in vivo* translocation, using the exchange method after a single injection of E_2 (2.5 μ g/mouse), revealed a rapid decrease in cytoplasmic receptor content accompanied by a concomitant increase in nuclear receptor content. Greater nuclear receptor content was identified in nuclei from BALB/c mice than in those from Z mice 45 min after E_2 injection. The binding behavior of the E_2 -receptor complexes to nuclei was studied by KCl extraction. The percent extracted from the nuclei of Z strain mice was significantly greater than that from the BALB/c strain at all KCl concentrations tested. Cross-over experiments in a cell-free system suggest that the difference in binding is due to differences in chromatin rather than in nuclear estrogen-receptor complexes. The greater nuclear receptor content and its stronger binding to chromatin might explain the higher susceptibility of BALB/c mice to estrogen-induced phenomena, including neoplastic transformation. - 79-3338 **Endometrial Pathology and Estrogens.** (Eng) Rosenwaks, Z. (Dept. Obstetrics and Gynecology, Div. Reproductive Endocrinology, State Univ. New York at Stony Brook, Health Sciences Center, Stony Brook, NY 11794); Wentz, A. C.; Seegar Jones, G.; Urban, M. D.; Lee, P. A.; Migeon, C. J.; Parmley, T. H.; Woodruff, J. D. *Obstet Gynecol* 53(4): 403-410; 1979.

Between 1954 and 1977, endometrial biopsies were obtained from 46 hypogonadal patients (44 with gonadal dysgenesis; 2 panhypopituitary) who were receiving estrogen-progestogen therapy. The age of the patients ranged from 16 to 46 yr (mean 24.3 yr), and the mean duration of therapy ranged from 5 mo to 22 yr (mean, 86 mo). The estrogen therapy consisted of Premarin or diethylstilbestrol; most patients received medroxyprogesterone acetate as the progestational agent. Four patients received estrogen treatment alone. Endometrial abnormalities occurred only in patients receiving a total lifetime conjugated estrogen dose of $\geq 2,500$ mg and who had received estrogen treatment for a period >4.2 yr. The biopsy outcome was significantly related ($p < 0.01$) to estrogen dose at the time of biopsy and to the total lifetime dose ($p < 0.05$). The progestational drugs administered did not protect against the development of endometrial abnormalities. None of the abnormal endometrial patterns were associated with abnormal vaginal bleeding. A cytological study of 1,685 cervical and vaginal smears

from 1,500 women using oral contraceptives (OC) and of 1,000 smears from 1,000 control women not using such contraceptives is described. The frequency of benign abnormal smears (ie, abnormalities of the malpighian layer, basal layer, and columnar epithelium) was 1,028/1,685 vs 561/1,000. The incidence of metaplasia in the two groups was 494/1,685 and 319/1,000, respectively. Mild dysplasia was found in 54 women using OC and in 8 controls; the respective incidences of moderate dysplasia were 6 and 3. Severe dysplasia (malignant cells) was found in 1 OC user and in 3 controls; this difference could not be evaluated statistically due to the number of patients involved. Spontaneous regression of the abnormal cytological changes was seen in most cases after cessation of OC use. (37 refs)

79-3349 Spontaneous Rupture of a Liver Cell Adenoma after Long Term Methyltestosterone: Report of a Case Successfully Treated by Emergency Right Hepatic Lobectomy. (Eng) Bird, D. (Carey Coombes Res. Fellow, Dept. Surgery, Bristol Royal Infirmary, Bristol, England); Vowles, K.; Anthony, P. P. *Br J Surg* 66(3): 212-213; 1979.

A case of spontaneous rupture of a liver cell adenoma in a 39-yr-old female-to-male transsexual who had received 150 mg/day methyltestosterone (MT) for 7 yr is reported. An emergency right hepatic lobectomy was performed successfully. Histologic examination also revealed peliosis hepatis. 17- α -Alkylated androgenic-anabolic steroids such as MT may cause abnormalities of standard liver function tests and cholestatic jaundice, and they have been implicated in the development of hepatic adenoma or hepatocellular carcinoma. It has been suggested that a single pathological process (hyperplasia, related perhaps to the anabolic effects of MT) could be responsible for both peliosis and the formation of nodules and tumors. Since treatment in transsexuals must be life-long, further cases

such as the one reported here can be expected. It is hoped that virilizing drugs other than 17- α -alkylated steroids can be used. (19 refs)

The effects of daily and weekly sc treatment with azathioprine (ATP) or isophosphamide (IPA) over periods of 14 or 16 mo on survival, glomerulonephritis, antinuclear antibodies (ANA), blood cell counts, and tumorigenesis in female (NZB x NZW) mice were studied. ANA titers were significantly reduced by daily ATP and daily or weekly IPA; weekly ATP had no significant effect on ANA titers. IPA significantly increased survival time in a dose-dependent fashion at doses of 0.2 or 0.4 mg daily or weekly. At 0.2 mg/day, ATP also increased survival time, but 0.4 mg/day produced significant mortality due to anemia; weekly ATP did not prolong survival. At low daily doses, ATP and IPA produced glomerular lesions in all mice within 20 mo. Glomerulonephritis was also induced in a high percentage of mice treated intermittently or at high daily doses with ATP or IPA. Both ATP and IPA caused a significant, dose-dependent increase in malignant lymphomas. Most tumors appeared after long-term treatment (at least 10 mo). Intermittent IPA treatment was as oncogenic as daily high-dose treatment. In contrast, intermittent ATP produced results statistically comparable to those of the control group. It is not known whether the cytotoxic agents themselves or the immunosuppression they induce initiated tumor formation. (32 refs)

79-3357 New Leukemia in the Course of Therapy of Acute Lymphoblastic Leukemia. (Eng) Ravindranath, Y. (Children's Hosp. of Michigan, 3901 Beaubien Blvd., Detroit, MI 48201); Inoue, S.; Considine, B.; Lusher, J.; Zuelzer, W. W. *Am J Hematol* 5(3): 211-223; 1978.

The development of a second, morphologically different leukemia was observed recently in three acute lymphoblastic leukemia (ALL) patients while on therapy. The second leukemias occurred 23, 27, 30 mo after initial remission induced with vincristine, 6-mercaptopurine, and prednisone. All three were receiving systemic chemotherapy, including methotrexate, and prophylactic fractional irradiation (100 rads) to the CNS. The second leukemias involved one case of juvenile chronic myelogenous leukemia (JCML) and two cases of acute myeloblastic leukemia, as diagnosed by the usual morphologic criteria including the presence of Auer rods in one. In two patients, a cytogenetically new clone was detected in the remission

marrow 10 and 12 mo preceding the overt change in clinical status. These three cases demonstrate that second leukemias occur in ALL patients and that some late relapses fall into this category. The possible etiologic role of modern intensive treatment methods in the development of second leukemia is discussed. (35 refs)

79-3358 Relationship Between Levodopa Therapy and Malignant Tumors. (Swe) Botteri, A. (Langvardskliniken, Sundsvalls sjukhus, S-851 86 Sundsvall, Sweden); Nordstrom, P. O. *Lakartidningen* 76(5): 316-317; 1979.

The literature on the possible relationship between malignant melanoma and L-dopa [3-(3,4-dihydroxyphenyl)-L-alanine] treatment for Parkinson's disease is reviewed, and a new case is reported. Activation of malignant melanoma or unusually high activity of melanoma was observed in many patients during or shortly after L-dopa treatment, which suggests a possible causal relationship between malignant melanoma and L-dopa, but the relationship cannot be definitely proved in view of the unpredictable clinical course of melanoma. L-Dopa, which is a physiological intermediate in melanin synthesis, may facilitate the growth of melanoma. Melanocytes are able to transform L-dopa into melanin via tyrosinase. Increased secretion of somatotropin, which can stimulate the activity of melanocytes, was observed during L-dopa treatment. A 73-yr-old woman with Parkinsonism was treated with L-dopa (max daily dose 0.8 g) for about 2 yr, during which time she developed uterine melanoma. A recurrent melanoma was found in the vulva after excision of the primary tumor. (15 refs)

79-3361 Diffuse Metanephric Adenoma after In Utero Aspirin Intoxication. A Unique Case of Progressive Renal Failure. (Eng) Bove, K. E. (Children's Hosp. Res. Foundation, Children's Hosp. Medical Center,

Cincinnati, OH); Bhatena, D.; Wyatt, R. J.; Lucas, B. A.; Holland, N. H. *Arch Pathol Lab Med* 103(4): 187-190; 1979.

Diffuse persistent glomerular immaturity and focal proximal tubular ectasia were seen in bilateral open renal biopsy specimens from a male infant with fluid and salt depletion and slowly progressive renal failure. The pregnancy was complicated by a maternal suicide attempt at 2 mo gestation by ingestion of 19 g aspirin. The baby's nursery course was uncomplicated, but he was hospitalized at ages 6 and 10 wk for failure to thrive. During the first year, severe renal rickets developed despite treatment. Subsequently, diffuse tubulopapillary renal adenoma subtotally replaced each kidney, thereby necessitating renal transplantation at age 7. Origin of diffuse metanephric adenoma from persistent primitive epithelium of the proximal nephron is postulated and partly substantiated. It is proposed that this case of persistent proximal nephronic epithelial immaturity and diffuse metanephric adenoma is a variant of nephroblastomatosis and that the first trimester suicide attempt with aspirin may have initiated the maturation defect that preceded neoplastic transformation. (13 refs)

79-3362 Effect of Hepatocarcinogens on the Adenine Purine Nucleotide Cycle During the Initiation Phase of Carcinogenesis. (Eng) Smith, L. D. (H. L. Snyder Memorial Res. Foundation, Winfield, KS 67156); Emerson, R.; Nixon, L. K. *Cancer Res* 39(6, part 1): 2132-2138; 1979.

The activities of the purine nucleotide cycle enzymes, ie, adenylosuccinate (SAMP) synthetase, SAMP lyase, and adenosine 5'-monophosphate (AMP) deaminase, were determined in hepatic tissues of female Sprague-Dawley rats fed and/or given ip injections of 3'-methyl-4-dimethylaminoazobenzene (3'-Me-DAB), 4'-methyl-4-dimethylaminoazobenzene (4'-Me-DAB), thioacetamide, ethionine, or 2-acetylaminofluorene (2-AAF). SAMP lyase activity showed an early increase in rats fed diets containing 0.06% of the hepatocarcinogens. AMP deaminase activity increased with 3'-Me-DAB and thioacetamide but not with ethionine or 2-AAF. SAMP synthetase activity was either unaffected or was inhibited by the carcinogens. Increases in SAMP lyase activity were noted as early as 48-72 hr following ip injections of thioacetamide and ethionine (each 50 mg/kg/day). The response of this enzyme was not duplicated by carcinogenic analogs such as 4'-Me-DAB or methionine. These data imply the interaction of active carcinogens with SAMP lyase and to some extent with AMP deaminase or with some mechanism responsible for their synthesis and/or release. This interaction may be a significant component of the initiation phase of carcinogenesis. (20 refs)

Preneoplastic to Neoplastic Change in Azodye-induced Carcinogenesis (Meeting Abstract). (Eng) Fiala, S. (Veterans Admin. Medical Center, Martinsburg, WV 25401); Ostrander, H.; Trout, E. C. *Proc Am Assoc Cancer Res* 20: 82; 1979 (no refs)

79-3364 Role of Nutritional Factors During a Complex Social-Hygienic Examination of Female Aniline Dye Workers. (Rus) Podluzhnyi, P. A. (Medical Inst., Perm', USSR). *Gig Sanit* (1): 44-47; 1979.

The role of various vocational-hygienic and social-hygienic factors, including nutritional regimen and dietary habits, in the development of genital organ pathology was studied in a group of 1,264 female aniline dye workers. The women were 25-39 yr old, all were married, and all had a duration of exposure >5 yr. A matching group of female workers who had not been exposed to aniline dyes served as controls. Compared with the control group, the aniline dye workers had a greatly increased incidence of menstrual-ovarian function disorders (26.41% vs 3.34%), inflammatory diseases of the genital organs (22.01% vs 11.66%), and precancerous conditions of the genital organs (10.69% vs 6.67%). Analysis of dietary habits showed that gynecological morbidity was significantly greater in workers who did not adhere to a regular nutritional regimen (ie, they had only 1-2 meals per day and irregular intervals between meals). 79-3365 Recent Data on the Examination of the Mutagenic Effect of a Dinitro-o-cresol-containing Pesticide by Different Test Methods. (Eng) Nehez, M. (Inst. Hygiene and Epidemiology, Szeged Univ. Medicine, Szeged, Hungary); Selyes, A.; Paldy, A.; Berencsi, G. *Ecotoxicol Environ Saf* 2(3/4): 243-248; 1978.

The mutagenic effect of the 50% dinitro-o-cresol (DNOC)-containing pesticide Krezonit E was assayed by several methods. Human WBC cultures were incubated for 72 hr with 0.02, 0.2, or 2.0 μ g/ml DNOC. The percentage of aberrations increased with increasing concentration (56.4% at 0.02 to 74.5% at 2.0 μ g/ml). Chromatid-type aberrations were dose-dependent, but chromosome-type aberrations were not. CFLP white male mice were given DNOC in two doses regimens. Ten mice were given a single 20-mg/kg dose ip. Other groups of mice were given DNOC ip at doses of 1.0, 5, or 10 mg/kg on days 1, 3, 5, and 9 of the experiment. Bone marrow preparations were prepared 24 hr after the last administration. The subchronic dose had a more harmful effect on bone marrow cells than the single dose. The rate of aberrant cells increased from 75% for the single dose or the chronic 1.0-mg/kg dose to 95% for the chronic 10-mg/kg dose. Gametic mutations were studied in 12-wk-old male mice treated with a single 10-mg/kg dose of

CHEMICAL CARCINOGENESIS

DNOC ip. Only gametic aberrations occurred in the control group, but gametic and autosomal aberrations were observed in the treated group. Significantly higher results were obtained on postinjection day 20, which indicates that the pesticide has a harmful effect on spermatogonia. The dominant lethal values were significantly higher in the sixth week. The rate of aberrations in F_1 embryonic chromosomes was significantly higher in the first, second, and third weeks after treatment of the male parent than in the control group. It is concluded that Krezonit E is mutagenic in human WBC cultures in vitro, in mouse bone marrow chromosomes in vivo, and in mouse germ cells. (18 refs)

- 79-3366 Study of Potential Carcinogenicity of m-Toluenediamine. (Rus) Pylev, L. N. (Cancer Res. Center, Moscow, USSR); Koval'skaia, G. D.; Genin, V. A. *Gig Sanit* (2): 37-41; 1979.

The potential carcinogenicity of m-toluenediamine (MTD) was evaluated in random-bred albino rats and CC57 mice. MTD was given either sc (rats: 1-8 mg in 0.5 ml saline 1x/wk; mice: 2 mg in 0.2 ml saline 1x/wk) or intragastrically (rats: 0.5-4 mg in 0.5 ml saline 5x/wk for 16 mo and then 3x/wk; mice: 2 mg in 0.2 ml saline 5x/wk for 16 mo and then 3x/wk). The sc administration of MTD induced tumors in 9/25 rats (3 had reticulosis, 5 had fibroadenoma of the mammary gland, and 1 had an adrenal tumor) and in 14/25 mice (12 had leukemia, and 2 had a lung tumor). The av latent period of tumor development was 16 and 5.5 mo and the av duration of survival was 19 and 14 mo in rats and mice, respectively. The intragastric administration of MTD induced tumors in 8/36 rats (2 had leukemia, 5 had fibroadenoma of the mammary gland, and 1 had an abdominal tumor) and in 10/55 mice (all 10 had leukemia). The av latent period of tumor development was 12.5 and 3.5 mo and the av duration of survival was 20 and 6.5 mo in rats and mice, respectively. (6 refs)

- 79-3369 The Mutagenicities of Safrole, Estragole, Eugenol, trans-Anethole, and Some of Their Known or Possible Metabolites for *Salmonella typhimurium* Mutants. (Eng) Swanson, A. B. (McArdle Lab. Cancer Res., Univ. Wisconsin Medical Sch., Madison, WI 53706); Chambliss, D. D.; Blomquist, J. C.; Miller, E. C.; Miller, J. A. *Mutat Res* 60(2): 143-153; 1979.

The mutagenicity of safrole, estragole, anethole, and eugenol and some of their known or possible metabolites toward *Salmonella typhimurium* strains TA1535, TA100, and TA98 was determined. Highly purified 1'-hydroxyestragole (HEG) and 1'-hydroxysafrole (HS) were mutagenic (approx 15 and 10 revertants/micromole (μ mol), respectively) for TA100 in the absence of NADPH-fortified liver microsomes; trans-anethole and estragole appeared to have very weak activity. 3'-Hydroxyanethole was too toxic to be evaluated. Supplementation with fortified rat liver microsomes and cytosol converted 3'-hydroxyanethole to a mutagen(s) and increased the mutagenicity of HEG, HS, estragole, and anethole for TA100. No mutagenicity was detected for safrole or eugenol with or without the fortified liver preparations. The electrophilic 2',3'-oxides of safrole, HS, 1'-acetoxysafrole, 1'-oxosafrole, estragole, HEG, and eugenol showed dose-dependent mutagenic activities for TA1535 in the absence of fortified liver microsomes. These mutagenicities ranged from about 330 revertants/ μ mol for 1'-oxosafrole-2',3'-oxide to about 7,000 revertants/ μ mol for safrole-2',3'-oxide. The arylalkenes, their hydroxylated derivatives, or their epoxides were not mutagenic toward TA98, except for 1'-oxosafrole-2',3'-oxide, which had weak activity. Since the arylalkenes are hydroxylated and/or epoxidized by hepatic microsomes, hydroxy and epoxide derivatives appear to be proximate and ultimate mutagenic metabolites, respectively, of the arylalkenes. - 79-3371 Proposed Feed and Food Additive Tolerances for 4-Amino-6-(1,1-dimethylethyl)-3-(methylthio)-1,2,4-triazin-5(4H)-one. (Eng) Taylor, R. (Office Pesticide Programs, Registration Div., TS-767, Environmental Protection Agency, E. Tower, 401 M St., SW, Washington, DC 20460). *Fed Regist* 44(89): 26750-26751; 1979.

It is proposed that tolerances for residues of the herbicide

4-amino-6-(1,1-dimethylethyl)-3-(methylthio)-1,2,4-triazin-5(4H)-one in the milled fractions of barley and wheat (excluding flour of both grains) be established at 3 ppm. (no refs)

- 79-3372 Tolerances and Exemptions from Tolerances for Pesticide Chemicals in or on Raw Agricultural Commodities; 4-Amino-6-(1,1-dimethylethyl)-3-(methylthio)-1,2,4-triazin-5(4H)-one. (Eng) Taylor, R. (Registration Div. (TS-767), Office Pesticide Programs, Environmental Protection Agency, 401 M St., SW, Washington, DC 20460). *Fed Regist* 44(89): 26743-26744; 1979.

Tolerances for residues of the herbicide 4-amino-6-(1,1-dimethylethyl)-3-(methylthio)-1,2,4-triazin-5(4H)-one were established at 0.75 ppm on barley grain and wheat grain, at 1 ppm on barley straw and wheat straw, and at 2 ppm on wheat forage. Toxicological data supporting the proposed tolerances included rat acute po lethal dose studies, rabbit and rat teratogenicity studies, 2-yr dog and rat feeding studies, an 18-mo mouse carcinogenicity study (negative at 2,500 ppm, the highest level fed), a three-generation rat reproduction study, and a mouse mutagenicity study. - 79-3373 Ames Test of 1-(X-Phenyl)-3,3-dialkyltriazenes. A Quantitative Structure-Activity Study. (Eng) Venger, B. H. (Dept. Chemistry, Pomona Coll., Claremont, CA 91711); Hansch, C.; Hatheway, G. J.; Amrein, Y. U. *J Med Chem* 22(5): 473-476; 1979.

The mutagenicity of 1-(X-phenyl)-3,3-dialkyltriazenes was tested in the Ames test with *Salmonella typhimurium* strain TA92, and a quantitative structure-activity relationship (QSAR) was formulated. The equation is based on 17 congeners and has a correlation coefficient of 0.974. The QSAR for mutagenicity was compared with the QSAR for antileukemia action and toxicity (LD₅₀) in mice. In addition, the mutagenicity of aflatoxin B₁ and the antitumor drug 5-(3,3-dimethyl-1-triazeno)imidazole-4-carboxamide (DTIC) was determined. Increasing lipophilicity and increased electron release via through resonance were found to increase mutagenicity. There was a 16,000-fold range in the mutagenicity of the triazenes, and an equation is given that can predict the potency within a factor of ± 2 . These results provide preliminary evidence that quantitative comparisons of mutagenicity can be made via the Ames assay. Mutagenicity was much more sensitive than antitumor activity to the electronic effect of substituents, but the reason for this is not clear. The differentiated electronic effects may be related to the bacterial DNA that is presumably being attacked. In mice, both gross toxicity and antitumor activity showed the same dependence on the electronic effects

of substituents. Among the triazenes, the species attacking DNA in mutagenesis or antileukemic activity is shown to be a carbonium ion. By manipulating the electronic and lipophilic character of the substituents, much could be done to decrease mutagenicity without destroying the pharmaceutical properties of a drug. Aflatoxin B₁ was about 10⁷ times (on the scale used) more mutagenic than DTIC. (20 refs)

79-3381 Effect of Dietary Dieldrin on Aflatoxin B₁ Carcinogenesis in Rainbow Trout (*Salmo gairdneri*). (Eng) Hendricks, J. D. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR 97331); Putnam, T. P.; Sinnhuber, R. O. *J Environ Pathol Toxicol* 2(3): 719-728; 1979.

The effects of the cyclodiene pesticide dieldrin on the mixed-function-oxidase system and on aflatoxin B₁ (AFB₁) carcinogenesis were determined in rainbow trout. Six-week-old trout were fed four semipurified diets for 12 mo. The four diets were formulated as follows: control diet (CD), CD + 6 ppb AFB₁, CD + 5 ppm dieldrin, and CD + 6 ppb AFB₁ + 5 ppm dieldrin. Samples were taken at 1, 2, 4, 6, 9, and 12 mo to determine growth, dieldrin accumulation, tumor incidence, and histopathology. Growth rate was depressed by 5 ppm dieldrin and to a greater extent by 6 ppb AFB₁. The diet containing both compounds produced growth similar to the 5-ppm dieldrin diet. Dieldrin accumulated rapidly during the first 2 mo of feeding to approx 0.9 ppm (whole-fish basis). The rate of accumulation was slower over the following 10 mo, resulting in tissue levels of approx 1.6 ppm at 12 mo. Dieldrin exerted a slight, perhaps questionable, cocarcinogenic effect with AFB₁. The 12-mo incidence of hepatocellular carcinomas was 8% higher in the AFB₁ + dieldrin diet group than in the AFB₁-positive controls; however, the significance of this increase was low ($p < 0.1$). The number of tumors/liver and tumor diameters were both slightly greater in fish fed the AFB₁ + dieldrin diet, but neither parameter was significant due to high variability. No tumors were seen in fish fed either the CD or the diet containing dieldrin alone. No histopathology was produced by this level of dieldrin. (23 refs)

79-3384 Aflatoxin B₁ and Aflatoxicol Metabolism in Rainbow Trout (*Salmo gairdneri*) and the Effects of Dietary Cyclopropene. (Eng) Loveland, P. M. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR 97331); Nixon, J. E.; Pawlowski, N. E.; Eisele, T. A.; Libbey, L. M.; Sinnhuber, R. O. *J Environ Pathol Toxicol* 2(3): 707-718; 1979.

The results of continuing work on the metabolism of aflatoxin B₁ in rainbow trout (*Salmo gairdneri*) are reported. Aflatoxin M₁ (AFM₁) was identified as a minor metabolite formed by the in vitro incubation of AFB₁ with the postmitochondrial fraction or microsomes from rainbow trout liver. Fresh, whole trout liver converted perfused AFB₁ to aflatoxicol (AFL) and AFM₁, and converted perfused AFL to AFB₁ and AFM₁. AFB₁ reductive activity was found in the 105,000 x g supernatant, but activity converting AFL to AFB₁ was distributed about equally in the 105,000 x g supernatant and in the microsomal pellet. Transformation of AFL to AFB₁ was not inhibited by CO, but formation of AFM₁ was completely blocked. Fish fed cyclopropene fatty acids (CPFA) produced only one-half to one-third as much AFL from AFB₁ as controls, and they produced no detectable AFM₁. Most of the unreacted AFB₁ was recovered by extraction of the incubation medium by organic solvent, whereas in controls, much of it remained bound to the protein. There was no difference in conversion of AFL to AFB₁ when results were expressed in terms of postmitochondrial protein levels. CPFA-fed fish had lower microsomal protein and cytochrome P-450 levels and lower NADPH-cytochrome c reductase and aldrin epoxidation activities than did controls. (22 refs)

79-3385 Effects of the Aflatoxins on ATPase Activities in Mouse and Rat Liver. (Eng) Desai, D. (Dept. Pharmacology and Toxicology, Univ. Mississippi Medical Center, Jackson, MS 39216); Phillips, T. D.; Hayes, A. W.; Ho, I. K. *J Environ Sci Health [B]* 14(3): 265-278; 1979.

The effects of the aflatoxins on ATPase activities in Male ICR mouse and male Sprague-Dawley rat tissues were investigated in vitro. The hepatic oligomycin-sensitive (OS) Mg⁺⁺ ATPase was inhibited significantly. The order of inhibition was aflatoxins G₁ > B₁ > G₂ > B₂. Mouse OS Mg⁺⁺ ATPase was more sensitive than the corresponding rat enzyme. The oligomycin-insensitive (OI) Mg⁺⁺ ATPase activities in rat and mouse liver were not altered. Although aflatoxin G₁ (AFG₁) and aflatoxin B₁ (AFB₁) were the more

potent inhibitors of hepatic OS Mg^{++} ATPase, no concentration-response was observed. In contrast, AFG₁ and AFB₂ inhibited enzyme activity in a concentration-dependent manner. Spectral analysis of AFG₁ solns suggested that solubility was not related to the observed effects. In addition, the effects of AFB₁ and AFG₁ on mouse brain microsomal Na^+-K^+ ATPase were examined. Although AFB₁ was more potent than AFG₁, both mycotoxins significantly inhibited enzyme activity in a concentration-dependent fashion. (26 refs)

- 79-3386 Antibacterial Activity of Zearalenone.** (Fre) Boutibonnes, P. (Laboratoire de Physiologie bacterienne II, Universite de Caen, Caen, France). *Can J Microbiol* 25(3): 421-423; 1979.

The antibacterial activity of zearalenone was limited to some gram-positive aerobic sporulating bacteria, especially *Bacillus thuringiensis* (Berliner). In this species, zearalenone decreased cell division and induced atypical cells. These effects resemble those seen with aflatoxin B₁ and patulin. (12 refs)

- 79-3389 Bioassay of Emetine for Possible Carcinogenicity.** (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (43): 1-108; 1978.

The possible carcinogenicity of emetine, an amebicide and anticancer drug, was investigated in rats and mice. Groups of 35 Sprague-Dawley rats of each sex were inoculated ip with 0.5 or 1 mg/kg emetine 3x/wk for 52 wk. Groups of 35 B6C3F1 mice of each sex were treated with 1.6, 3.2, or 6.4 mg/kg emetine 3x/wk for 52, 52, and 28 wk (males) and for 52, 40, and 33 wk (females), respectively, with increasing dose. The high-dose male rats were observed for 31 wk and all other rats for 32 wk after treatment, with only 9 high-dose males surviving to the end of the study com-

pared with 32 low-dose males, 29 low-dose females, and 24 high-dose females. Increased mortality was even more marked in mice: only 14 low-dose males and 8 low-dose females survived to the end of the 26-wk posttreatment observation period; only 2 mid-dose males survived >52 wk; and all high-dose males, mid-dose females, and high-dose females died during treatment. There was a variety of tumors in the treated rats, but none occurred at a statistically significant incidence in comparison with the controls. In male rats, tumor incidences were 13/27, 5/35, and 3/10, respectively, in the low-dose, high-dose, and control rats examined histopathologically; in females, these incidences were 26/35, 22/35, and 7/10. The mid-dose and high-dose male mice and mid-dose female mice died before the appearance of tumors. There were 7/35 and 6/48 high-dose and control tumor-bearing male mice, respectively, and 2/34, 1/27, and 3/50 low-dose, high-dose and control tumor-bearing female mice, respectively; there was no statistical significance to the differences among these groups. Because the treatment and observation periods were shorter than those usually employed in bioassays of this type and because of the poor survival among the treated mice, it is concluded that the results do not allow evaluation of the possible carcinogenicity of emetine. (23 refs)

- 79-3390 Bioassay of Ethionamide for Possible Carcinogenicity.** (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (46): 1-86; 1978.

To evaluate the carcinogenicity of ethionamide (EA), a synthetic antitubercular drug, chronic feeding studies were carried out in 41-day-old Fischer 344 rats and 70-day-old B6C3F1 mice following subchronic feeding studies in male Sprague-Dawley rats and Swiss mice to establish max tolerated doses. Groups of 34 or 35 rats of each sex were fed 1,500 or 3,000 ppm EA 5 days/wk for 78 wk, and groups of 34 or 35 mice of each sex were fed 1,000 or 2,000 ppm EA 5 days/wk for 78 wk. All animals were observed for an additional 25-26 wk and were killed and necropsied when moribund or at the end of the experiment. Only animals surviving >100 days were evaluated. The only toxic sign in the animals was a lower mean body wt compared with that of controls. A variety of neoplasms was observed in both the treated and control rats of both sexes, but they were types commonly found in Fischer 344 rats. None of the tumor incidences in treated rats was statistically significant compared with control levels. The incidences of malignant lymphomas in mice were 8/34 and 4/34 in low- and high-dose males, respectively, and 4/31 and 10/34 in low- and high-dose females, respectively. They were slightly but not significantly higher than control levels (2/15 and 2/15 for males and females, respectively). There was a variety of other neoplasms in both experimental and control mice with no significant differences between the groups. It is

concluded that, under the conditions of this bioassay, EA was not carcinogenic in either Fischer 344 rats or B6C3F1 mice. (13 refs)

79-3391 Bioassay of Thio-TEPA for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (58): 1-168; 1978.

The carcinogenicity of thio-TEPA (triethylene thiophosphoramide) was studied in Sprague-Dawley rats and B6C3F1 mice. The animals were inoculated ip with 0.7, 1.4, or 2.8 mg/kg (rats) or 1.15 or 2.3 mg/kg (mice) 3x/wk for a max of 52 wk. The experiments were terminated at 81-87 wk (rats) or at 86-87 wk (mice). Thio-TEPA was toxic to both species, causing reduced wt gain and early deaths in the middle-dose (MD) and high-dose (HD) rats and HD mice. Since all HD rats died by 21 wk, microscopic examination of the tissues was performed only in the low-dose (LD) and MD groups. The tumor incidence rates were time-adjusted. Under these conditions, thio-TEPA was carcinogenic in both species at all evaluable doses. Rats had a significantly increased frequency of squamous cell carcinomas (SCC) of the skin or ear canal (both sexes) and hematopoietic neoplasms (males). Mice showed a significantly increased frequency of SCC of the skin and associated glands (males) and lymphocytic leukemia or lymphomas (both sexes). Uterine adenocarcinomas were also increased in female rats (7/21 MD and 2/33 LD rats; none in controls). Treated rats also showed a non-significantly increased frequency of neuroepitheliomas (neuroblastomas) or nasal carcinomas (3/34 LD males, 2/33 LD females, and 2/21 MD females). Since no neuroepitheliomas or nasal carcinomas were seen in 380 control Sprague-Dawley rats of both sexes in other bioassays, they may be associated with administration of thio-TEPA. It is concluded that, under the conditions of this bioassay, thio-TEPA was carcinogenic in both Sprague-Dawley rats and B6C3F1 mice. (20 refs)

79-3392 Bioassay of Estradiol Mustard for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (59): 1-116; 1978.

The carcinogenicity of the experimental anticancer agent estradiol mustard (EM) was investigated in groups of 35 Sprague-Dawley rats and 34-36 B6C3F1 mice of each sex. The animals received 0.62 or 1.25 mg/kg (rats) or 15 or 30 mg/kg (mice) by gavage 3x/wk for 52 wk. They were observed for an additional 30-34 wk, except that the high-dose (HD) female mice were all dead or sacrificed by 24 wk after the end of treatment. Survival was adequate in all

groups for animals to be at risk for late-developing tumors; however, the increased mortality after 40 wk in the HD male and female mice may have limited late tumor development. Survival in the low-dose (LD) and HD animals, respectively, at the end of the study was 32 and 26 male rats, 25 and 21 female rats, 12 and 9 male mice, and 12 and 0 female mice. In mice but not in rats, there were some statistically significant tumor incidences in each test group compared with controls: lymphoma and lymphocytic leukemia (6/32 vs 0/28), lung adenoma and carcinoma (12/30 vs 2/28), and myocardial sarcoma (6/30 vs 0/28) in LD males; lymphoma and lymphocytic leukemia (17/29 vs 0/28) in HD males; lymphoma (9/30 vs 1/30), lung adenoma and carcinoma (7/27 vs 1/28), and myocardial sarcoma (8/27 vs 0/28) in LD females; and lymphoma (1/23 vs 1/30) in HD females. Also, squamous cell carcinoma of the stomach occurred in 2/29 HD male mice and 2/26 LD and 2/14 HD female mice but it was absent in all controls and in >500 male and >500 female historical-control mice, indicating that these gastric tumors were related to EM. The overall tumor incidences in LD, HD, and control animals, respectively, were 10/35, 10/33 and 9/19 male rats, 27/34, 26/33, and 12/18 female rats, 24/32, 23/29, and 10/29 male mice, and 25/30, 20/24, and 2/30 female mice. It is concluded that, under the conditions of this bioassay, EM was not carcinogenic in Sprague-Dawley rats but was carcinogenic in both male and female B6C3F1 mice. (20 refs)

79-3393 Bioassay of Phenoxybenzamine Hydrochloride for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (72): 1-90; 1978.

The carcinogenicity of the antihypertensive agent phenoxybenzamine hydrochloride (PBH) was investigated in groups of 35 Sprague-Dawley rats and B6C3F1 mice of each sex. The animals were inoculated ip with 5 or 10 mg/kg (rats or 12.5 or 25 mg/kg (mice) 3x/wk for 52 wk. All the high-dose (HD) male mice were dead by 50 wk, with 39 wk being the median survival time (MST). All the HD female mice died by 54 wk (MST 43 wk). The low-dose (LD) mice were observed until 83-84 wk, with 19 males and 25 females being alive at the end of the study. All HD male rats died by 58 wk (MST 43 wk); LD males had a MST of 69 wk, with 13 being alive at the end of the study (83 wk). HD and LD female rats were observed until 83-84 wk, with 23 and 12, respectively, being alive at the end of the study. In rats, the incidence of peritoneal sarcoma (PS) was significant in all but the LD females, being 11/31, 16/20, and 16/30 in LD and HD males and HD females, respectively; PS did not occur in controls. The incidence of PS was also significant in HD mice: 17/21 males and 16/33 females had this lesion, but it did not occur in controls. Other tumors occurred in both treated and control animals,

but none were found at significant incidences in dosed animals in comparison with controls. Overall tumor incidences for LD, HD, and control animals, respectively, were 15/31, 16/20, and 5/20 male rats, 20/35, 20/30, and 12/19 female rats, 7/30, 18/21, and 10/29 male mice, and 7/33, 16/20 (all PS's) and 9/28 female mice. It is concluded that, under the conditions of this bioassay, PBA was carcinogenic for both sexes of Sprague-Dawley rats and B6C3F1 mice, causing PS's. (18 refs)

79-3394 Report on the Bioassay of Chlorobenzilate for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (75): 1-45; 1978.

The carcinogenicity of the pesticide chlorobenzilate (CB) was investigated in chronic feeding studies in groups of 50 Osborne-Mendel rats and B6C3F1 mice of each sex. The rodents were fed CB either continuously for 78 wk or continuously for a certain period and then in a pattern of 1 wk off followed by 4 wk on for varying lengths of time (discontinuous dosing); the total treatment time was 72-78 wk. Male rats received 1,600 ppm continuously or a time-weighted av dose (TWAD) of 2,995 ppm discontinuously for 73 wk; female rats received 1,175 ppm continuously or a TWAD of 2,229 ppm discontinuously for 74 wk; survivors were sacrificed at 110-111 wk. Male mice received TWAD's of 4,231 ppm for 78 wk or 7,846 ppm discontinuously for 72 wk; female mice received 3,200 ppm continuously or 5,908 ppm discontinuously for 72 wk; survivors were sacrificed at 90-91 wk. Survival was adequate in all low-dose (LD) and high-dose (HD) groups, with 29 and 34 male rats, 38 and 36 female rats, 34 and 41 male mice, and 43 and 44 female mice being alive, respectively, at the termination of each study. Tumor incidences in the LD, HD, and control groups were 31/50, 23/50, and 28/49 male rats, 38/48, 34/48, and 36/50 female rats, 34/47, 25/45, and 5/17 male mice, and 18/49, 15/50, and 5/20 female mice. The only statistically significant finding, compared with controls, was the higher incidence of adrenal cortical adenomas in LD males (7/50 vs 0/49) and HD females (5/48 vs 0/50). In mice, only the incidence of hepatocellular carcinoma was statistically significant, compared with controls (4/17 males and 0/20 females), in the LD and HD (32/47 males, 11/49 females and 22/45 males, 13/50 females, respectively). It is concluded that, under the conditions of this bioassay, CB was carcinogenic in male and female B6C3F1 mice but that insufficient evidence was obtained to demonstrate the carcinogenicity of CB in Osborne-Mendel rats. (17 refs)

79-3395 Bioassay of ICRF-159 for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer

Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (78): 1-100; 1978.

The experimental anticancer drug ICRF-159[(±)bis-4,4'-(1-methyl-1,2-ethanediyl)-2,6-piperazinedione] was tested for carcinogenicity in Sprague-Dawley rats and B6C3F1 mice. The animals were inoculated ip with 48 or 96 mg/kg (rats) or 40 or 80 mg/kg (mice) 3x/wk for 52 wk. The experiment was terminated at 81-86 wk in rats and 86 wk in mice. Mortality was dose-related in male mice and in rats of both sexes. The high mortality rate in male rats may have been associated with inflammatory diseases of the pleural and peritoneal cavities, lungs, and liver. The tumor incidence rate was time-adjusted for male rats. Under these bioassay conditions, ICRF-159 caused a dose-related increase in the occurrence of tumors in female rats (uterine adenocarcinomas) and female mice (lymphomas), but it was not significantly carcinogenic in males of either species. (17 refs)

79-3396 Bioassay of Trimethylphosphate for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (81): 1-98; 1978.

The carcinogenicity of trimethyl phosphate (TMP), an alkylating agent used as a gasoline additive, was investigated in groups of 50 Fischer 344 rats and groups of 49-50 B6C3F1 mice of each sex. TMP was administered 3x/wk by gavage in distilled water at doses of 50 or 100 mg/kg (rats) and 250 or 500 mg/kg (mice) for 103-104 wk. Rats were observed 1 wk beyond the end of dosing, mice only to the end of dosing. Survival was adequate in all test groups for the animals to be at risk for late-developing tumors. All rats survived at least 52 wk, and at 105 wk there were 28 and 17 males and 36 and 27 females alive in the low-dose (LD) and high-dose (HD) groups, respectively. At 103 wk, the respective figures for mice were 44 and 39 males and 31 and 29 females. The only statistically significant tumor incidences in dosed animals in comparison with controls were those of sc fibromas in HD male rats (9/49 vs 0/20) and of uterine/endometrial adenocarcinomas in female mice (13/37 vs 0/16). The overall tumor incidences in LD, HD, and control animals, respectively, were 48/50, 43/49, and 19/20 male rats, 40/50, 42/49, and 15/20 female rats, 26/50, 26/49, and 11/20 male mice, and 28/50, 30/49, and 11/20 female mice. It is concluded that, under the conditions of this bioassay, TMP was carcinogenic in male Fischer rats and female B6C3F1 mice, but not carcinogenic in female Fischer rats or male B6C3F1 mice. (24 refs)

79-3397 Bioassay of Daminozide for Possible Carcinogenicity. (Eng) National Cancer In-

stitute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (83): 1-114; 1978.

The carcinogenicity of the plant growth regulator daminozide (DOZ) was investigated in 104-wk feeding studies using groups of 50 Fischer 344 rats and B6C3F1 mice of each sex given doses of 5,000 or 10,000 ppm. The experiment was terminated at 105 wk by sacrifice of the survivors in the low-dose (LD) and high-dose (HD) groups, which were, respectively, 37 and 44 male rats, 35 and 39 female rats, 38 and 32 male mice, and 32 and 30 female mice. Survival in all groups was adequate for the animals to be at risk for late-developing tumors. In the male rats, only the incidence of testicular interstitial cell tumors was significantly higher than that in the controls, but because these lesions occur at a high spontaneous rate in this strain, the result is probably not attributable to DOZ. In female rats, the incidences of endometrial adenocarcinomas and uterine leiomyosarcoma in the LD and HD groups (5/50 and 3/50; 1/50 and 3/50, respectively) were below statistical significance in comparison with controls, but because these lesions were absent in the controls and occurred with low incidence in historical controls, they are probably associated with DOZ. Although the incidence of hepatocellular carcinoma in HD male mice (13/46) was statistically significant compared with controls, there was a high incidence of this lesion in historical-control rats, so that its appearance in the test rats is not clearly associated with DOZ. There was a large variety of tumors in all test animals, but none of the other results was statistically significant compared with controls. Tumor incidences in LD, HD, and control animals examined histopathologically were 50/50, 49/50, and 16/20 male rats, 32/50, 28/50, and 11/20 female rats, 28/50, 37/46, and 8/14 male mice, and 27/41, 25/48, and 13/20 female mice. It is concluded that, under the conditions of this bioassay, DOZ was not carcinogenic in male Fischer 344 rats or female B6C3F1 mice, that it induced endometrial adenocarcinomas and uterine leiomyosarcomas in female Fischer 344 rats, and that it may have been associated with the hepatocellular carcinomas in male B6C3F1 mice. (18 refs)

79-3398 Bioassay of 2,4-Diaminoanisole Sulfate for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (84): 1-69; 1978.

The carcinogenicity of 2,4-diaminoanisole (DAA), a hair-dye component, was investigated by chronic feeding studies in groups of 50 Fischer 344 rats and B6C3F1 mice of each sex. DAA was mixed into the diet at a concentration of 0.12% or 0.5% (rats) or 0.12% or 0.24% (mice) for 78 wk, followed by observation periods of 29 wk (rats) and 18-19 wk (mice). Five animals from each test group except the low-dose (LD) male and female mice were sacrificed in

week 78; survival in all dosed groups was adequate for animals to be at risk for late-developing tumors. At 106-107 wk, survival in the LD and high-dose (HD) groups, respectively, was 30 and 27 female rats, 29 and 22 female rats, 46 and 41 male mice, and 38 and 39 female mice. None of the tumor incidences in any LD group was statistically significant compared with controls, except that of malignant lymphoma in LD female mice (14/45 vs 5/48). In the HD male rats there were several significant results in comparison with controls: thyroid C-cell adenoma or carcinoma (10/49 vs 1/48), thyroid carcinoma (14/49 vs 0/48), thyroid papillary adenocarcinoma, follicular cell carcinoma, or papillary cystadenoma (17/49 vs 0/48), preputial gland neoplasms (8/49 vs 0/48), Zymbal's gland neoplasms (8/49 vs 0/48), and skin squamous cell or basal cell carcinoma or sebaceous adenocarcinoma (7/49 vs 0/48). Among HD female rats, the statistically significant tumor incidences were those of thyroid adenocarcinoma, follicular cell carcinoma, or papillary cystadenocarcinoma (10/49 vs 1/45), and Zymbal's gland sebaceous adenocarcinoma (7/49 vs 0/50). In HD male and female mice, only the incidence of thyroid follicular cell adenoma was statistically significant when compared with controls (11/45 vs 0/40 in males, 8/45 vs 0/41 in females). In the HD female mice, the incidence of malignant lymphoma (9/50) was marginally significant compared with controls (2/45). The overall tumor incidences in the LD, HD, LD control, and HD control animals, respectively, were 48/48, 47/49, 34/46, and 44/48 male rats, 44/49, 37/49, 32/49, and 38/50 female rats, 24/49, 33/49, 17/48, and 22/49 male mice, and 25/44, 30/50, 20/47, and 10/50 female mice. It is concluded that, under the conditions of this bioassay, DAA was carcinogenic to both sexes of Fischer 344 rats and B6C3F1 mice. (29 refs)

79-3399 Bioassay of 4-Chloro-m-phenylenediamine for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (85): 1-46; 1978.

The carcinogenicity of 4-chloro-m-phenylenediamine (CMPD), a dye intermediate, was investigated by chronic feeding studies in groups of 49-50 Fischer 344 rats and B6C3F1 mice of each sex. The animals received 0.2% or 0.4% (rats) or 0.7% or 1.4% (mice) CMPD in their diets for 78 wk and were observed for an additional 26-27 wk (rats) or 17 wk (mice). Survival was adequate in all test groups for the animals to be at risk for late-developing tumors. Five animals in each high-dose (HD) group were sacrificed in week 78. At the end of the study, survival in the low-dose (LD) and HD groups, respectively, was 43 and 36 for male rats, 39 and 33 for female rats, 41 and 40 for male mice, and 37 and 38 for female mice. The only statistically significant tumor incidence in rats was that of adrenal pheochromocytoma in HD male rats (14/48) compared with controls (4/46). In LD female rats, the in-

cidence of uterine endometrial stromal polyps (12/48) was statistically significant compared with controls (2/48), but it was lower than that in HD females (5/46) or historical controls (31/249), so that this result was not attributed to CMPD. None of the tumor incidences in male mice was statistically significant compared with controls, but in LD and HD female mice, the combined incidence of hepatocellular adenomas and carcinomas (11/44 and 8/45, respectively) was significant compared with controls (0/46). The overall tumor incidences in the LD, HD, and control groups, respectively, were 46/49, 46/49, and 42/48 male rats, 33/50, 30/47, and 27/50 female rats, 19/49, 25/48, and 22/50 male mice, and 20/44, 16/46, and 14/47 female mice. It is concluded that, under the conditions of this bioassay, CMPD was carcinogenic to male Fischer 344 rats and female B6C3F1 mice, but not to female Fischer 344 rats or male B6C3F1 mice. (21 refs)

79-3400 Bioassay of 1H-Benzotriazole for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (88): 1-116; 1978.

The carcinogenicity of 1H-benzotriazole (HBT), an anticorrosive chemical, was investigated by chronic feeding studies in groups of 50 Fischer 344 rats and B6C3F1 mice of each sex. Time-weighted av concentrations of HBT were administered in the diets by the following dose schedules: 6,700 or 12,100 ppm for 78 wk (rats), and 11,700 or 23,500 ppm for 104 wk (mice). Rats were observed for an additional 26-27 wk, mice for an additional 2 wk. Survival was adequate in all groups for the animals to be at risk for late-developing tumors. At the end of the study, survival in the low-dose (LD) and high-dose (HD) groups, respectively, was 34 and 36 for male rats, 40 and 43 for female rats, 36 and 42 for male mice, and 39 and 47 for female mice; 5 rats in each HD group were sacrificed in week 78. None of the tumor incidences in rats or mice was statistically significant compared with test and/or historical controls. In HD male rats, the incidence of neoplastic liver nodules (5/45) was significantly higher than that in the controls (0/48), but 2/13 historical controls had this tumor. In LD female mice, the incidence of alveolar/bronchiolar carcinomas and the combined incidence of alveolar/bronchiolar adenomas and carcinomas (9/49 and 10/49) were significant compared with controls (0/49), but the incidence in the HD group was not significant and the incidence in historical controls varied from 0 to 7% (av: 4%), so that these tumors could not be clearly related to HBT. The overall tumor incidences in LD, HD, and control groups, respectively, were 43/46, 40/46, and 42/48 male rats, 27/48, 30/50, and 27/50 female rats, 23/44, 18/48, and 24/39 male mice, and 25/49, 14/50, and 21/49 female mice. It is concluded that, under the conditions of this bioassay, there was no convincing evidence that HBT was carcinogenic in Fischer 344 rats or B6C3F1 mice of either sex. (25 refs)

79-3401 Bioassay of o-Anisidine Hydrochloride for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (89): 1-130; 1978.

The carcinogenicity of o-anisidine (OA), which is used in dye manufacture, was investigated by chronic feeding studies in groups of 55 Fischer 344 rats and B6C3F1 mice. OA was administered in the diets at doses of 5,000 or 10,000 ppm for 83-103 wk (rats) or 2,500 or 5,000 ppm for 103 wk (mice); mice and low-dose (LD) rats were observed or an additional 1-2 wk. Considerable dose-related mortality occurred in rats: all high-dose (HD) males and females were dead by 83 and 88 wk, respectively, only 7 LD males were alive at 104 wk, and the last LD female died at 103 wk. Survival in mice was adequate for the animals to be at risk for late-developing tumors. In rats, the incidence of transitional cell carcinoma of the bladder and the combined incidence of transitional cell carcinoma and papilloma of the bladder were statistically significant in all groups compared with controls; the respective figures were 50/54, 52/54, and 0/51 in LD males, 51/52, 52/52, and 0/51 in HD males, 41/49, 46/49, and 0/49 in LD females, and 50/51, 50/51, and 0/49 in HD females. In LD and HD male rats, the incidences of thyroid follicular cell tumors (7/40 and 6/40, respectively) and of thyroid adenomas, cystadenomas, or papillary adenomas (4/40 and 4/40, respectively) were statistically significant compared with controls (0/53 and 0/53, respectively). In HD male rats, the incidence of kidney or kidney pelvis transitional cell carcinomas (7/53) was statistically significant compared with controls (0/53). None of the tumor incidences in LD male or female mice was statistically significant in comparison with controls, but in the HD males and females, the combined incidence of transitional cell carcinomas or papillomas of the bladder (22/53 and 22/50, respectively) were statistically significant compared with controls (0/48 and 0/50). The overall tumor incidences in LD, HD, and control groups, respectively, were 53/55, 53/53, and 54/54 male rats, 50/53, 51/54, and 52/54 female rats, 27/55, 30/53, and 43/55 male mice, and 20/52, 33/54, and 34/55 female mice. It is concluded that, under the conditions of this bioassay, OA was carcinogenic for Fischer 344 rats and B6C3F1 mice of both sexes. (21 refs)

79-3402 Report on the Bioassay of Dicofol for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (90): 1-46; 1978.

The carcinogenicity of dicofol (DC), a synthetic organochlorine acaricide, was investigated by chronic feeding studies in groups of 50 Osborne-Mendel rats and B6C3F1 mice of each sex. DC, dissolved in corn oil, was mixed with the diet at a time-weighted av concentration of

CHEMICAL CARCINOGENESIS

471 or 942 ppm in male rats, 380 or 760 ppm in female rats, 264 or 528 ppm in male mice, and 122 or 243 ppm in female mice for 78 wk, followed by 34 wk of observation in rats and 14-15 wk in mice. Survival was adequate in all test groups for the animals to be at risk for late-developing tumors. Survival among low-dose (LD) and high-dose (HD) rats, respectively, at 100 wk was 32 and 36 for males and 46 and 44 for females; the respective figures for mice at 92-93 wk were 38 and 38 for males and 42 and 48 for females. Although there were several different tumors in both the dosed and control groups, the only statistically significant incidence compared with controls was that of hepatocellular carcinoma in the HD male mice (35/47 vs 3/18). The overall tumor incidences in LD, HD, and control animals, respectively, were 23/49, 16/47, and 10/19 male rats, 28/49, 28/49, and 16/20 female rats, 34/48, 38/47, and 5/18 male mice, and 5/20, 6/44, and 8/50 female mice. It is concluded that, under the conditions of this bioassay, DC was carcinogenic in male B6C3F1 mice, but not carcinogenic in female B6C3F1 mice or in male or female Osborne-Mendel rats. (26 refs)

79-3403 Bioassay of Hydrazobenzene for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (92): 1-58; 1978.

The carcinogenicity of hydrazobenzene (HB) were investigated by chronic feeding studies in groups of 50 male and 47-50 female Fischer 344 rats and B6C3F1 mice. The male rats received a time-weighted av concentration of 0.008% or 0.03% HB and the female rats received 0.004 or 0.01% HB in their diets for 78 wk, followed by 28-30 wk of observation before sacrifice. The male mice received a time-weighted av concentration of 0.008% or 0.04% HB and the female mice received 0.004 or 0.04% HB in their diets for 78 wk, followed by 17-18 wk of observation. Survival was adequate in all groups for the animals to be at risk for late-developing tumors. Five rats in each group and five mice in each high-dose group were sacrificed at 78 wk. At 100 wk, the survival in the low- and high-dose rat groups, respectively, was 39 and 32 males and 37 and 25 females; at 95-96 wk, the respective survival in the mouse groups was 44 and 39 males and 37 and 26 females. The only statistically significant tumor incidences in comparison with controls were those of hepatocellular carcinoma in low-dose male rats (5/49 vs 0/47), hepatocellular carcinoma (31/49 vs 1/48) and squamous cell carcinoma of zymbal's gland (5/49 vs 0/48) in high-dose male rats, mammary gland adenocarcinoma (6/50 vs 0/50) and neoplastic liver nodules (6/50 vs 0/50) in high-dose female rats, and hepatocellular carcinoma in high-dose female mice (20/43 vs 1/50). The overall tumor incidences in the low- and high-dose test groups and the low- and high-dose control groups, respectively, for animals examined histopathologically were 48/49, 47/49, 47/47, and 44/48

for male rats, 39/50, 36/50, 42/47, and 38/50 for female rats, 18/47, 17/46, 23/50, and 22/49 for male mice, and 19/39, 29/43, 18/47, and 10/50 for female mice. It is concluded that, under the conditions of this bioassay, HB was carcinogenic to Fischer 344 rats of both sexes and to female B6C3F1 mice, but that it was not carcinogenic to male B6C3F1 mice. (22 refs)

79-3404 Bioassay of Phenazopyridine Hydrochloride for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (99): 1-98; 1978.

To investigate the carcinogenicity of phenazopyridine hydrochloride (PPH), chronic feeding studies were undertaken in groups of 35 Fischer 344 rats and B6C3F1 mice of each sex. The animals received 3,700 or 7,500 ppm (rats) or 600 or 1,200 ppm (mice) in their diets 5 days/wk for 78 wk and were observed until 104-107 wk. Survival was adequate in all test groups for the animals to be at risk for late-developing tumors. The numbers of survivors at the end of the study in the low-dose (LD) and high-dose (HD) groups, respectively, were 25 and 28 male rats, 30 and 28 female rats, 26 and 25 male mice, and 26 and 21 female mice. Adenocarcinomas of the large intestine (colon and rectum) occurred in male and female rats at statistically significant frequencies in comparison with controls (4/34, 9/33, and 0/14 males and 3/33, 5/32, and 0/14 females for LD, HD, and control groups, respectively). The other tumors that were found in dosed rats were not significant in comparison with controls. The overall tumor incidences in the LD, HD, and control rats, respectively, were 29/34, 17/35, and 14/14 males and 10/33, 13/32, and 5/15 females. None of the tumor incidences in male mice was significant compared with controls. In LD female mice there was a dose-related trend in the incidence of hepatocellular adenomas and carcinomas (11/34) compared with controls (1/15), and in the HD females the incidence of these tumors (21/32) became significant. The overall tumor incidences in female mice were significant. The overall tumor incidences in LD, HD, and control mice, respectively, were 17/35, 20/34, and 7/15 male mice and 20/34, 27/32, and 8/15 female mice. It is concluded that, under the conditions of this bioassay, PPH was carcinogenic in Fischer 344 rats, causing adenocarcinomas of the large intestine in males and females, and in female B6C3F1 mice, causing hepatocellular adenomas and carcinomas, but that it was not carcinogenic in male B6C3F1 mice. (17 refs)

79-3405 Bioassay of Anilazine for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (104): 1-99; 1978.

The carcinogenicity of the fungicide anilazine (AAZ) was investigated by chronic feeding studies in groups of 50 Fischer 344 rats and B6C3F1 mice of each sex given 500 or 1,000 ppm AAZ dissolved in a small amount of acetone and added to their diets for 103 wk. Surviving animals were sacrificed at 103-104 wk (rats) or 107-109 wk (mice). Survival was adequate in all groups for the animals to be at risk for late-developing tumors. At 2 yr, survival in the low- and high-dose groups, respectively, was 37 and 37 for male rats, 37 and 34 for female rats, 40 and 44 for male mice, and 33 and 41 for female mice. The survival data and the fact that only the dosed male mice exhibited a decreased gain in mean body wt indicate that the rats and the female mice may have been able to tolerate higher doses of AAZ. There was a variety of tumors in both the experimental and control groups, but none of the tumors in the dosed animals occurred at incidences that were significantly higher than those in the corresponding controls. Respective tumor incidences in the low-dose, high-dose, and control animals that were examined histopathologically were 50/50, 50/50, and 24/25 in male rats, 42/50, 43/50, and 22/25 in female rats, 20/49, 25/50, and 15/23 in male mice, and 22/47, 18/50, and 4/25 in female mice. It is concluded that, under the conditions of this bioassay, AAZ was not carcinogenic in Fischer 344 rats and B6C3F1 mice. (31 refs)

79-3406 Bioassay of m-Cresidine for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (105): 1-54; 1978.

The carcinogenicity of m-cresidine (MC), a dyestuff intermediate, was investigated in groups of 49-50 Fischer 344 rats and B6C3F1 mice of each sex. MC was dissolved in corn oil and administered by gavage 5x/wk: rats received 0.08 or 0.16 g/kg for 77 wk; mice received 0.08 or 0.16 g/kg for 32 wk and then 0.02 or 0.04 g/kg, respectively, for 21 wk (the time-weighted av doses were 0.06 and 0.11 g/kg, respectively). Rats were observed for an additional 32-33 wk, mice for an additional 25-41 wk. Survival was adequate in all groups but the male mice for animals to be at risk for late-developing tumors. At the end of the study, there were 31 and 24 male rats and 28 and 22 female rats alive in the low-dose (LD) and high-dose (HD) groups, respectively, with 5 animals having been sacrificed in each HD group in wk 78. Median survival time in LD and HD male mice, respectively, was 52 and 26 wk; 15 LD mice were alive at 93 wk, and all HD mice were dead by 78 wk. At 94 wk, there were 43 and 30 LD and HD female mice alive, respectively. None of the tumor incidences in mice was statistically significant compared with controls; overall tumor incidences in LD, HD, and pooled controls, respectively, were 10/45, 0/36, and 29/73 males and 10/50, 15/46, and 15/74 females. None of the tumor incidences in rats was statistically significant compared with controls,

but the incidences of papillary transitional-cell carcinomas of the bladder in HD males (5/44), LD females (1/46), and HD females (2/44) compared with pooled controls (0/148) and the rarity of this tumor in historical controls indicate that this tumor was MC-related. The overall tumor incidences in LD, HD, and pooled control groups, respectively, were 41/47, 36/45, and 73/75 males and 38/49, 19/45, and 43/73 females. It is concluded that, under the conditions of this bioassay, MC was carcinogenic to Fischer 344 rats of both sexes, was not carcinogenic to female B6C3F1 mice, and cannot be evaluated for carcinogenicity to male B6C3F1 mice because of their high mortality while receiving the compound. (17 refs)

79-3407 Bioassay of Trichlorofluoromethane for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (106): 1-46; 1978.

The carcinogenicity of trichlorofluoromethane (TCFM), widely used aerosol propellant and refrigerant, was investigated in rats and mice that received TCFM by gavage as a 37.5-42.5% soln (rats) or a 20-40% soln (mice) in corn oil on 5 consecutive days/wk for a total of 78 wk. Groups of 50 Osborne-Mendel rats and B6C3F1 mice of each sex were dosed as follows: 425 or 850 mg/kg/day for 12 wk followed by 500 or 1,000 mg/kg/day, respectively, for 66 wk in male rats; 750 or 1,500 mg/kg/day for 12 wk followed by 500 or 1,000 mg/kg/day, respectively, for 66 wk in female rats; 1,580 or 3,160 mg/kg/day for 7 wk followed by 2,000 or 4,000 mg/kg/day, respectively, for 71 wk in both male and female mice. The time-weighted av doses in male and female rats were 488 and 977 and 538 and 1,077 mg/kg/day, respectively, those in mice were 1,962 and 3,925 mg/kg/day. Survival in rats was inadequate for the animals to be at risk for late-developing tumors; only 20 and 15 males and 31 and 17 females in the low- and high-dose groups, respectively, were alive at 52 wk, and <10% of the rats in any group survived to the end of the test (111 wk, except that the low-dose male test ended at 106 wk). Hence the rat tumor data are inconclusive; tumor incidences in the low-dose, high-dose, and control groups for animals examined histopathologically were 4/50, 1/50, and 11/40 in males and 4/49, 7/50, and 16/40 in females. The survival of the treated mice was adequate to evaluate risk from late-developing tumors; at the end of the study (91 wk), the respective low- and high-dose group survival was 41 and 29 in male and 37 and 32 in females. There was a variety of tumors in both treated and control mice, but the tumors in the dosed mice did not occur at significant incidences compared with controls. The respective tumor incidences in low-dose, high-dose, and control mice examined histopathologically were 22/50, 16/47, and 11/37 in males and 11/50, 9/49, and 6/37 in females. No conclusion can be drawn with regard to the carcinogenicity of TCFM in Osborne-Mendel rats. It is concluded that, under the

conditions of this bioassay, TCFM was not carcinogenic to male or female B6C3F1 mice. (31 refs)

79-3408 Report on the Bioassay of 5-Nitro-o-Toluidine for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (107): 1-50; 1978.

The carcinogenicity of the azo dye intermediate 5-nitro-o-toluidine (NT) was investigated by chronic feeding studies in groups of 50 Fischer 344 rats and B6C3F1 mice of each sex. The rodents received a time-weighted av dose of 0.005% or 0.01% (rats) or 0.1% or 0.12% (mice) in their diets for 78 wk and were observed for an additional 30-31 wk (rats) or 19-20 wk (mice). Five animals in each group were sacrificed at 78-79 wk; survivors were sacrificed at the end of the observation periods. Adequate numbers in all test groups survived to the end of the study for the animals to be at risk for late-developing tumors. Survivors in the low-dose (LD) and high-dose (HD) groups, respectively, were 27 and 28 male rats, 28 and 33 female rats, 41 and 38 male mice, and 42 and 36 female mice. A variety of tumors occurred in all treated and control animals. None of the tumor incidences in dosed rats were statistically significant compared with controls; tumor incidences in the LD, HD, and control rat groups, respectively, were 37/46, 42/47, and 47/47 males and 33/47, 35/50, and 42/47 females. In mice, only the incidence of hepatocellular carcinoma was statistically significant when the HD groups were compared with controls (29/45 vs 12/50 in males and 20/45 vs 2/47 in females). The combined incidence of hemangiomas and hemangiosarcomas in HD male mice (4/48) and the incidence of hemangiosarcomas in LD female mice (5/47) were considered attributable to NT because, although these incidences were not significant in comparison with the untreated controls, they were significant in comparison with historical controls in the same laboratory (5/350). The overall tumor incidences in the LD, HD, and control mice, respectively, were 20/46, 31/48, and 23/50 males and 19/47, 25/47, and 18/47 females. It is concluded that, under the conditions of this bioassay, NT was not carcinogenic in Fischer 344 rats, but it caused hepatocellular carcinomas in both male and female B6C3F1 mice as well as an increased incidence of hemangiomas and hemangiosarcomas in male B6C3F1 mice and hemangiosarcomas in female B6C3F1 mice. (26 refs)

79-3409 Bioassay of 3-Amino-4-ethoxyacetanilide for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (112): 1-52; 1978.

The carcinogenicity of 3-amino-4-ethoxyacetanilide (AEA), an azo dye intermediate, was investigated by chronic feeding studies in groups of 48 or 50 Fischer 344 rats and B6C3F1 mice. AEA was administered to the animals at 0.4% or 1.5% (rats) or 0.4% or 0.8% (mice) of their diet for 78 wk. Rats were observed for an additional 28-35 wk, mice for an additional 16-18 wk. Survival was adequate in all groups for animals to be at risk for late-developing tumors. At the end of the study, the low-dose (LD) and high-dose (HD) group survival, respectively, was 32 and 41 in male rats, 32 and 37 in female rats, 48 and 38 in male mice, and 48 and 38 in female mice. None of the tumor incidences in rats was statistically significant compared with controls. The only statistically significant result in mice was the higher incidence of follicular cell carcinoma of the thyroid in HD male mice (7/45) compared with controls (0/45). The overall tumor incidences in LD, HD, LD controls, and HD controls, respectively, were 46/46, 46/50, 44/48, and 42/47 male rats, 37/46, 30/49, 38/50, and 42/47 female rats, 28/49, 19/47, 22/49, and 19/46 male mice, and 31/50, 21/47, 10/50, and 17/47 female mice. Many of the confidence intervals in the statistical analyses of tumor incidence in rats have an upper limit >1, indicating a theoretical possibility of tumor induction in rats by AEA that was not established by this test. It is concluded that, under the conditions of this bioassay, AEA was carcinogenic for male B6C3F1 mice, but that there was insufficient incidence to establish carcinogenicity in male or female Fischer 344 rats. (22 refs)

79-3410 Bioassay of 2,3,5,6-Tetrachloro-4-Nitroanisole for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (114): 1-54; 1978.

The carcinogenicity of 2,3,5,6-tetrachloro-4-nitroanisole (TCNA) was investigated in chronic feeding studies in groups of 50 Fischer 344 rats and groups of 55 B6C3F1 mice of each sex. Dose levels, established in prior sub-chronic toxicity tests, were 0.006% or 0.012% for 104 wk. Because the high-dose male rats were incorrectly sexed, a second group of 25 rats was treated at the high dose level for 104 wk to give a total of 49 male rats subjected to this regimen. Survivors were sacrificed 105-107 wk after the initiation of feeding. Survival was adequate in all groups for the animals to be at risk for late-developing tumors; at the termination of the study, there were, in the low- and high-dose groups, respectively, 46 and 38 male rats, 48 and 39 female rats, 49 and 50 male mice, and 47 and 46 female mice. Tumor incidences in the low-dose, high-dose and control animals in each group that were examined histopathologically were 48/49, 43/48, and 42/49 male rats, 34/50, 28/45, and 27/50 female rats, 38/54, 36/52, and 43/55 male mice, and 37/54, 38/52 and 34/55 female mice. The only statistically significant results, compared

with controls, were the incidences of interstitial cell testis tumors in male rats and the combined incidence of leukemia and malignant lymphoma in male mice. However, these lesions were considered to be unrelated to the administration of TCNA because such tumors occur spontaneously in these strains with a high and variable incidence. It is concluded that, under the conditions of this bioassay, dietary administration of TCNA was not carcinogenic in Fischer 344 rats or B6C3F1 mice of either sex. (19 refs)

79-3411 Bioassay of p-Anisidine Hydrochloride for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (116): 1-52; 1978.

To investigate the carcinogenicity of p-anisidine (AD), a chronic feeding study was undertaken in groups of 55 Fischer 344 rats and B6C3F1 mice of each sex, after the max tolerated dose had been determined in a subchronic toxicity test. Rats were fed 0.6% or 0.3% and mice were fed 1.0% or 0.5% AD in their diet for 103 wk, followed by an observation period of 2-3 wk for rats and 3 wk for mice. Adequate numbers of animals in all groups survived sufficiently long to be at risk for late-developing tumors. Animals alive at the end of the experiment consisted of 43 low-dose and 45 high-dose male rats, 43 low-dose and 50 high-dose female rats, 48 low-dose and 50 high-dose male mice, and 42 low-dose and 43 high-dose female mice. There was a variety of tumors in all treated animals and controls. Tumor incidences were 50/54, 50/55, and 54/54 male rats, respectively, in the low-dose, high-dose, and control animals examined histopathologically. Corresponding values were 38/43, 42/50, and 52/54 female rats, 29/54, 36/50, and 43/55 male mice, and 33/54, 24/50, and 34/55 female mice. In male rats, there were significant positive associations between AD administration and the incidences of both squamous cell carcinomas of the skin and alveolar/bronchiolar adenomas, but none of the Fischer exact comparisons supported these findings. The only statistically significant result in male rats was the Fisher exact comparison of the low-dose and control groups with respect to the combined incidence of adenomas and carcinomas of the preputial gland. There were no significant positive associations in any mice between compound administration and any tumor incidence. It is concluded that AD was not carcinogenic in B6C3F1 mice under the conditions of this bioassay, and that the evidence is insufficient to establish the carcinogenicity of AD in Fischer 344 rats. (20 refs)

79-3412 Bioassay of Dioxathion for Possible Carcinogenicity. (Eng) National Cancer In-

stitute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (125): 1-43; 1978.

The carcinogenicity of dioxathion (DX), an organophosphorus insecticide, was investigated in groups of 50 Osborne-Mendel rats and B6C3F1 mice of each sex in chronic feeding studies. The initial dose was increased after 31 wk in rats and after 17 wk in mice so that the time-weighted av dose received over 78 wk was 90 or 180 ppm in male rats, 45 or 90 ppm in female rats, 284 or 567 ppm in male mice, and 467 or 935 ppm in female mice. These doses were selected on the basis of prior subchronic toxicity tests to determine max tolerated doses. Survival was adequate in all test groups for the animals to be at risk for late-developing tumors. When the rat study was terminated at 111 wk, 23 and 25 males and 31 and 34 females were alive in the low- and high-dose groups, respectively. The corresponding figures for the mouse groups at 90-91 wk were 35 and 37 males and 46 and 45 females. A variety of neoplasms was observed in test animals of both species, but none of the tumors was histologically unusual, and no incidence was statistically significant in comparison with controls. Tumor incidences for low-dose, high-dose, and control groups, respectively, were 23/50, 21/49, and 28/49 in male rats, 27/47, 29/48, and 36/50 in female rats, 10/49, 13/49, and 7/19 in male mice, and 6/50, 6/48, and 2/18 in female mice. It is concluded that, under the conditions of this bioassay, dietary administration of DX was not carcinogenic in Osborne-Mendel rats or B6C3F1 mice. (17 refs)

79-3413 Bioassay of 2,5-Toluenediamine Sulfate for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (126): 1-50; 1978.

The carcinogenicity of 2,5-toluenediamine (TDA: sulfate form) was evaluated in groups of 50 Fischer 344 rats and B6C3F1 mice of each sex. The doses used in these chronic feeding studies were determined by the results of prior subchronic toxicity tests. Male rats were fed either 0.05% TDA for 14 wk, followed by 0.06% for 64 wk, or 0.2% for 78 wk and observed for an additional 28 and 30 wk, respectively. Female rats were fed according to the same regimens and observed for an additional 107 or 109 wk, respectively. Male and female mice were fed 0.06% or 0.1% TDA for 78 wk; low-dose animals were observed an additional 16 wk, high-dose animals an additional 19 wk. Survival was adequate in all test animals; 42 and 45 males and 42 and 43 females lived at least 85 wk in the low- and high-dose rat groups, respectively, and 47 and 37 males and 39 and 33 females lived to the end of the study in the low- and high-dose mice groups. Tumor incidence in the low-dose, high-dose, and two control groups, respectively, was 45/48, 48/49, 22/25, and 34/46 in male rats, 34/50, 33/50, 19/23,

CHEMICAL CARCINOGENESIS

and 32/49 in female rats, 19/48, 27/49, 21/45, and 17/48 in male mice, and 15/43, 22/46, 22/46, and 20/47 in female mice. The incidence of interstitial cell neoplasms of the testis in the male rats (43/48 low-dose and 47/49 high-dose rats) was statistically significant compared with controls (19/25 and 33/46), but it was not attributed to the administration of TDA because the spontaneous incidence of these tumors is high and variable in Fischer 344 rats. None of the results was statistically significant in the female rats, compared with controls. None of the results in test mice was statistically significant compared with controls except for an increased incidence of lung tumor in the high-dose females (8/46 vs 1/45), but this evidence was not considered convincing because the test and control mice were shipped and housed under different conditions. It is concluded that, under the conditions of this bioassay, sufficient evidence was not obtained to demonstrate the carcinogenicity of TDA in Fischer 344 rats or B6C3F1 mice. (23 refs)

79-3414 Bioassay of Aniline Hydrochloride for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (130): 1-55; 1978.

The carcinogenicity of aniline hydrochloride (AH), a dye intermediate, was investigated by chronic feeding studies in groups of 50 Fischer 344 rats and groups of 49-50 B6C3F1 mice of each sex. The animals were fed 0.3% or 0.6% (rats) or 0.6% or 1.2% (mice) AH in their diets for 103 wk and observed for an additional 4-5 wk. Survival was adequate in all groups for the animals to be at risk for late-developing tumors. At the end of the study, survival in the low-dose (LD) and high-dose (HD) groups, respectively, was 34 and 27 in male rats, 44 and 41 in female rats, 43 and 41 in male mice, and 37 and 41 in female mice. There was a variety of tumors in the dosed and control mice, but none of the tumor incidences in dosed mice was statistically significant in comparison with controls. Tumor incidences in LD, HD, and control mice, respectively, were 27/49, 22/49, and 24/39 males and 22/48, 28/49, and 21/49 females. In comparison with controls, the incidence of spleen hemangiosarcoma (19/50 vs 0/25) in LD male rats and the incidences of spleen fibrosarcoma or sarcoma (9/46 vs 0/25), spleen hemangiosarcoma (20/46 vs 0/25), and fibrosarcoma or sarcoma of multiple organs of the body cavities (9/48 vs 0/25) in HD male rats were statistically significant. None of the tumor incidences in LD female rats was statistically significant in comparison with controls, but in HD female rats, the combined incidence of sarcoma and fibrosarcoma of the spleen and of multiple organs of the body cavities (8/50 vs 0/24) was considered dose-related to AH. The overall tumor incidences in LD, HD, and control rats, respectively, were 27/49, 22/49, and 24/39 males and 22/48, 28/49, and 21/49 females. It is concluded that, under the conditions of this

bioassay, AH was carcinogenic to male and female Fischer 344 rats but not to B6C3F1 mice. (20 refs)

79-3415 Report on the Bioassay of Triphenyltin Hydroxide for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (139): 1-41; 1978.

The carcinogenicity of triphenyltin hydroxide (TPTH), a fungicide and insect-controlling compound, was investigated in chronic feeding studies in groups of 50 Fischer 344 rats and B6C3F1 mice of each sex. Animals were fed diets containing 37.5 or 75 ppm TPTH for 78 wk and observed for an additional 26 wk, at which time all survivors were sacrificed. Survival was adequate in all groups for the animals to be at risk for late-developing tumors; the survivors in the low-dose (LD) and high-dose (HD) groups, respectively, at 104 wk were 38 and 42 male rats, 40 and 45 female rats, 37 and 33 male mice, and 36 and 38 female mice. In male mice, there was a significant positive association between dose and mortality. In female mice and male rats, there was a slight depression of mean body wt gain, but no compound-related mean body wt depression was observed. In female rats there were no significant signs of toxicity due to TPTH. Thus, it is possible that TPTH was not administered at the max tolerated doses. There was a variety of tumors in both the control and treated animals, but no tumors occurred at a significantly higher incidence in dosed animals than in controls. The respective tumor incidences in LD, HD, and control animals examined histopathologically were 49/50, 50/50, and 18/20 male rats, 39/50, 31/50, and 12/20 female rats, 19/44, 22/45, and 10/20 male mice, and 15/42, 18/48, and 10/18 female mice. It is concluded that, under the conditions of this bioassay, TPTH was not carcinogenic in Fischer 344 rats or B6C3F1 mice. (17 refs)

79-3416 Bioassay of Pivalolactone for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (140): 1-48; 1978.

The carcinogenicity of pivalolactone (PVL), an intermediate in polymer synthesis, was investigated in groups of 50 Fischer rats and B6C3F1 mice of each sex that were treated with PVL in distilled water 3x/wk by gavage for 103 or 102 wk, respectively. The rats received 150 or 300 mg/kg PVL as a 1.5%-3.0% soln; the mice received 75 or 150 mg/kg as a 0.68%-1.36% soln. Among rats given the high PVL dose, 62% of the males and 56% of the females were alive at the end of 103 wk; corresponding survival rates in the low-dose group were 76% and 86%. Survival

rates for mice were 90% of males and 72% of females in the high-dose group and 84% of males and 72% of females in the low-dose group. The rats were observed for an additional 2 wk and the mice for 1 wk before sacrifice. PVL administration was associated with an increased incidence of squamous cell papillomas (scp's) and squamous cell carcinomas (scc's) of the forestomach in rats but not in mice. No other rare or unusual tumors were observed in either species. In the high-dose rats, the increase in forestomach tumors was statistically significant in both males and females. Scp's or scc's developed in 21/48 high-dose rats vs 6/49 low-dose rats and 0/19 controls. In female rats, the combined incidence of these tumors was 11/50 high-dose animals, 2/50 low-dose animals, and 0/20 controls. The results indicate that PVL is carcinogenic for Fischer 344 rats of both sexes but not for B6C3F1 mice. (21 refs)

- 79-3417 Report on the Bioassay of 1-Phenyl-3-methyl-5-pyrazolone for Possible Carcinogenicity.** (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (141): 1-43; 1978.

The carcinogenicity of 1-phenyl-3-methyl-5-pyrazolone (PMP) a widely used dye intermediate, was investigated by chronic feeding studies in groups of 49 or 50 male and 50 female Fischer 344 rats and B6C3F1 mice. The animals received 2,500 or 5,000 ppm (rats) or 7,500 or 15,000 ppm (mice) in their diet for 102-103 wk and were observed for 2 additional wk. The only toxic effect observed was a compound-related mean body wt depression in mice; hence, the compound may not have been administered to rats at the max tolerated dose. Survival was adequate in all test groups for the animals to be at risk for late-developing tumors. The numbers of survivors in the low-dose (LD) and high-dose (HD) groups, respectively, at the end of the study were 29 and 37 for male rats, 44 and 44 for female rats, 40 and 43 for male mice, and 38 and 34 for female mice. A variety of tumors was found in both treated and control animals, but none of the tumors in dosed animals occurred at a significant frequency compared with controls. Tumor incidences in LD, HD, and control animals, respectively, were 49/49, 49/50, and 19/19 male rats, 36/50, 25/50, and 12/20 female rats, 20/49, 14/50, and 11/18 male mice, and 19/49, 15/46, and 9/20 female mice. It is concluded that, under the conditions of this bioassay, there was no evidence for the carcinogenicity of PMP in Fischer 344 rats or B6C3F1 mice. (18 refs)

- 79-3418 Bioassay of 3-Chloro-p-toluidine for Possible Carcinogenicity.** (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer

Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (145): 1-43; 1978.

To investigate the carcinogenicity of 3-chloro-p-toluidine (CT), a dye intermediate and avicide, a chronic feeding study in rodents was undertaken using dose levels determined in a prior subchronic toxicity test. Groups of 50 Fischer 344 rats and 50 B6C3F1 mice of each sex were used. Male and female rats received time-weighted av doses of 1,635 or 3,269 ppm CT for 78 wk and were observed for an additional 25 wk (except the high-dose males, which were observed for 24 wk). Male mice received 600 or 1,200 ppm and female mice received 300 or 600 ppm CT for 78 wk and were observed for an additional 12 wk. Animals were sacrificed when moribund or at the end of the observation period and subjected to histopathologic examination; 47-50 animals in each group were evaluated. A large variety of tumors was found in all dosed and control animals, with no significant differences between the groups. Tumor incidences in rats were 49/49, 50/50, and 20/20 for low-dose, high-dose, and control males, respectively, and 22/50, 28/50, and 7/19 for low-dose, high dose, and control females respectively. Tumor incidences in mice were 15/49, 14/49, and 5/20 in low-dose, high-dose, and control males, respectively, and 6/50, 11/47, and 5/20 in low-dose, high-dose, and control females, respectively. Moreover, adequate numbers of animals in all groups survived sufficiently long to be at risk for late-developing tumors. It is concluded that, under the conditions of this bioassay, there was no convincing evidence for the carcinogenicity of CT. (18 refs)

- 79-3419 Report on the Bioassay of Mexacarbate for Possible Carcinogenicity.** (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (147): 1-49; 1978.

To investigate the carcinogenicity of the pesticide mexacarbate (MCB), chronic feeding studies were undertaken in Osborne-Mendel rats and B6C3F1 mice using groups of 50 animals of each sex. The chronic study comprised 78 wk of feeding plus 33-34 wk of additional observation in rats, 14-15 wk in mice. Male rats received 188 or 375 ppm MCB for 17 wk, followed by 215 or 430 ppm, respectively, for 61 wk; female rats received 300 or 600 ppm for 17 wk, followed by 350 or 700 ppm for 61 wk, respectively. The time-weighted av concentrations administered to these four groups were 209, 418, 339, and 678 ppm. Male mice received 225 or 450 ppm for 6 wk, followed by 275 or 550 ppm for 14 wk and then 350 or 700 ppm for 58 wk, respectively; female mice received 37 or 74 ppm for 6 wk, followed by 50 or 100 ppm for 14 wk and then 75 or 150 ppm for 58 wk, respectively. The time-weighted av concentrations administered to these four groups were 327, 654, 68, and 135 ppm. Survival was adequate in all experimental groups so

that the animals were at risk for late-developing tumors. There were no significant differences in the incidences of any tumor in the rats compared with controls. Female mice may not have received the max tolerated dose of MCB, because the compound had no significant effect on survival or body wt. The numbers of tumor-bearing rats were 21/49, 16/48, and 6/20 for low-dose (LD), high-dose (HD), and control males, respectively, and 33/50, 28/50, and 12/20 for the respective female groups. The respective results for tumor-bearing mice were 24/46, 28/47, and 0/15 males and 16/48, 13/48, and 5/20 females. In male mice that survived ≥ 56 wk, the Cochran-Armitage test showed significant associations between dietary concentration of MCB and the incidences of hepatocellular carcinoma, sc fibrosarcomas, and skin fibromas, but the Fischer exact test did not support any of these results. It is concluded that, under the conditions of this bioassay, insufficient evidence was obtained to establish the car-

cinogenicity of MCB to Osborne-Mendel rats or B6C3F1 mice. (20 refs)

PHYSICAL CARCINOGENESIS

- 79-3420 Ultraviolet B Phototherapy for Psoriasis in Sunlight-responsive Patients (Letter to Editor).** (Eng) Boer, J. (Dept. Dermatology, Univ. Hosp., Leiden, Netherlands); Schothorst, A. A.; Suurmond, D. *Lancet* 1(8119): 773; 1979.

UV B phototherapy [wavelength range 290-320 nanometers (nm)] has several advantages over PUVA therapy [psoralen + long-wave (320-400 nm) UV A light] for the treatment of psoriasis. These include the avoidance of po administration of photosensitizers and shorter exposure times. However, just as for PUVA treatment, the long-term risk-benefit ratio (oncogenic aspects) of UV B therapy must be investigated extensively before it can be recommended for use on a large scale. - 79-3421 Dithranol or Photochemotherapy for Psoriasis? (Letter to Editor).** (Eng) Howell, D. R. (Victoria General Hosp., Halifax, Nova Scotia, Canada). *Lancet* 1(8119): 772-773; 1979.

A previous paper in which dithranol therapy is compared with combined psoralen and long-wave UV (PUVA) treatment for chronic psoriasis is discussed. Some workers have reported that recurrences of psoriasis are relatively common after PUVA treatment; many patients require booster treatments every 1-2 wk, increasing the amount of exposure to long-wave UV light, with its attendant potential hazards (including skin cancer). (no refs)

- 79-3422 Topical Methoxsalen Administration and Sunlamp Fluorescent Irradiation in Psoriasis.** (Eng) Petrozzi, J. W. (Dept. Dermatology, 111-P, Philadelphia Veterans Admin. Hosp., University and Woodland Aves., Philadelphia, PA 19104); Barton, J. O.; Kligman, A.; de los Reyes, O. *Arch Dermatol* 115(4): 436-439; 1979.

Total resolution of psoriasis was achieved in 17/20 patients with corticosteroid-resistant disease treated with topical administration of psoralens and fluorescent light from a sunlamp. Resolution was achieved after an av of 18 treatments, and adverse blistering phototoxic reactions and excessive hyperpigmentation were not encountered. However, the potential risk of photocarcinogenicity makes this treatment experimental, and it should be reserved for recalcitrant cases. (15 refs)

- 79-3424 Correlation of In Vitro Transformation with In Vivo Tumorigenicity in 10T1/2 Mouse Cells Exposed to UV Light.** (Eng) Chan, G. L. (Lab. Radiology, Harvard Univ. Sch. of Public Health, Boston, MA 02115); Little, J. B. *Br J Cancer* 39(5): 590-593; 1979.

The correlation between tumorigenicity in vivo and the acquisition of anchorage independence for growth in vitro was studied using UV-irradiated (254 nanometers) C3H mouse embryo-derived 10T1/2 cells. Eight independent transformed foci were selected for cloning; the clones were scored as Types II or III. The criss-crossing cell morphology was seen only at the periphery of Type III foci. A correlation was demonstrated between Type III morphology and the ability to grow in soft agar; Type II cells required attachment to a solid substrate for growth. Type III cells also formed tumors following sc injection into C3H/HENMTV- mice. When 2×10^6 cells were injected, there was a 100% tumor take. The Type II foci failed to cause tumors in vivo. The results indicate that the Type III foci were malignant transformants. The transformation of a normal cell to a fully malignant one appears to be a multistep process, with the loss of contact inhibition of growth being an earlier step than morphologic change, anchorage independence, and tumorigenicity. - Cyclic AMP (cAMP)-dependent and cAMP-independent protein kinase activities were measured in cellular homogenates prepared from an x-radiation-induced mucoid adenocarcinoma of the Holtzman rat small bowel. These activities were compared with those in similar cell preparations of normal unirradiated small bowel tissues and with those in irradiated intestines that did not develop visible lesions. A significantly lower degree of cAMP-dependent endogenous and exogenous protein (histone) phosphorylation was observed in the cancer cells compared with that in other tissues. The activities of the enzymes in the tumor tissues, but not the other tissues, appeared to be independent of homogenate concentration. Similarly, cAMP stimulated only very slightly the malignant protein kinases, but significant stimulation occurred with the exogenous kinases of unirradiated small intestines and also of irradiated intestines without visible lesions. The results suggest that (1) the radiation-induced cancer consists of cells that no longer respond normally to extracellular signals that are transmitted intracellularly by the cAMP system or (2) greater phosphoprotein phosphatase activities exist in the cancer cells. - 79-3436 Correlation Between Radiological, Scintigraphic and Histological Changes in Bone Following Irradiation of Rabbits with Single and Fractionated Doses. (Ger) Burgener, F. A. (Dept. Radiology, Univ. Rochester Medical Center, Rochester, NY 14642); King, M. A.; Weber, D. A. *ROEFO* 130(3): 359-366; 1979.
- The results of radiologic, scintigraphic (SG), and histologic analyses of bone alterations in irradiated rabbits were compared. Male New Zealand albino rabbits were randomized into one of three treatment groups: (1) controls (4 rabbits),

(2) 1,750 rads to the hind leg (8 rabbits), and (3) 4,650 rads to the hind leg fractionated over 3 wk (8 rabbits). X-rays of the contralateral and the radiated legs were obtained up to 12 mo postirradiation (PI). Signs of radiogenic bone atrophy were first noticed 6 mo PI. They had developed gradually and they consisted of nonhomogeneous, spotty mineralization; endosteal scalloping; and pagetoid bone in 13/16 Group 2 and 3 rabbits. The findings were similar in both groups. SG studies with technetium-99m pyrophosphate showed that there was an increased uptake of label in Group 2 irradiated legs 1 day PI compared with control levels. One mo later, this difference was not detectable. Another large increase in uptake was found 3 mo later, and a slight increase remained at 6 mo. However, there was a decrease in uptake in most irradiated legs 1 yr PI. Uptake reached a peak at 3 wk in Group 3 irradiated legs and then fell rapidly, so that at 2 mo uptake was lower than that in control legs. Another uptake peak was found 3-4 mo PI. At 11-12 mo PI, uptake in the irradiated legs was decreased. In some Group 2 and 3 animals, a third uptake peak occurred during the second half of the first yr PI that was found to coincide with tumor appearance. Histological findings at 1 yr were similar for Groups 2 and 3. Bone sarcomas (5 proximal tibia, 1 distal femur) were found in four Group 2 rabbits and in two Group 3 rabbits. The four osteoblastic sarcomas were detectable 3-6 mo earlier by SG studies than by the x-ray studies. These tumors were characterized by the formation of new bone on the x-rays. Evidence for the two fibroblastic sarcomas was first seen by x-rays as bone destruction that progressed rapidly. SC evidence of these tumors first appeared 1-3 mo after x-ray evidence. The results indicate that the combined use of x-ray and SG studies should result in an earlier diagnosis of radiation-induced changes in bone than that obtained with either study alone. (15 refs)

79-3437 Risks of Exposure to X-Rays in Patients Undergoing Long-Term Treatment for Scoliosis. (Eng) Nash, C. L. (Univ. Hosps. Cleveland, 2065 Adelbert Road, Cleveland, OH 44106); Gregg, E. C.; Brown, R. H.; Pillai, K. *J Bone Joint Surg [Am]* 61A(3): 371-374; 1979.

A study was made to determine the current genetic and carcinogenic risks of x-radiation to scoliosis patients under treatment and to evaluate ways in which these risks could be minimized. Thirteen healthy teenage girls with idiopathic adolescent scoliosis were studied using multiple thermoluminescent dosimeters while undergoing standard diagnostic roentgenograms. Av organ doses for each anteroposterior and lateral examination were calculated for bone marrow, gastrointestinal tract, lungs, breast tissue, and gonads. Given an av of 22 roentgenograms over a 3-yr Milwaukee brace-treatment program, the increase in organ carcinogenic risk due to x-radiation ranged from 3.4 to 15/million (1.3%-7.5%), except for breast tissue, which increased from 140 to 290/million (110%). When

posteroanterior exposures were used instead of anteroposterior exposures, the increased risk was reduced to 5.3/million (3.8%). The genetic risks of scoliosis roentgenographic studies were considered to be negligible, especially with gonadal shielding and infrequent roentgenograms made every 3-4 months. Good technique and judicious ordering of roentgenograms added significantly to the safety of the patient. (8 refs)

79-3438 Conditions for Inhibiting and Enhancing Effects of the Protease Inhibitor Antipain on X-Ray-induced Neoplastic Transformation in Hamster and Mouse Cells. (Eng) Borek, C. (Radiological Res. Lab., Dept. Radiology, Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032); Miller, R.; Pain, C.; Troll, W. *Proc Natl Acad Sci USA* 76(4): 1800-1803; 1979.

The effect of the protease inhibitor antipain on x-ray-induced neoplastic transformation was investigated in two in vitro systems in short-term cultures of freshly explanted hamster embryo cells and in the heteroploid C3H mouse embryo cell line 10T1/2, clone 8. Although there was no effect on cell survival in both cell systems compared with irradiated controls, the addition of 6 µg/ml antipain to the cultures 24 hr prior to irradiation resulted in enhanced transformation, compared with the frequency in cultures exposed to radiation alone. In contrast, the addition of antipain to cultures 10 min after irradiation resulted in a decreased transformation rate. This decrease was not found when antipain was added to the mouse cells 24 hr after irradiation or to the hamster cells 48 hr after irradiation. These results suggest that the protease inhibitor antipain has more than one mechanism of action in modulating the fixation and expression of transformation by x-radiation, possibly by the modification of DNA repair. (32 refs)

79-3439 Radiation Carcinogenesis and Radiological Protection. (Eng) Dolphin, G. W. (Natl. Radiological Protection Board, Harwell, Didcot, Oxon OX11 0RQ, England). *Environ Res* 18(1): 140-146; 1979.

Theoretical and pragmatic methods of setting radiation dose limits are described. With the theoretical approach, it is assumed that the relationship between cancer risk in an organ or tissue and the radiation dose to that organ or tissue is linear and that there is no dose threshold. The slope of the line is believed to be adequately determined from the sparse data on cancer incidence observed in irradiated humans. The pragmatic approach is based on the fact that 25% of all deaths are due to cancer and that cancer is present in an even greater percentage of the population at death. The object of setting dose limits in this approach is to ensure that radiation exposure does not significantly increase the risk of dying from cancer and that

PHYSICAL CARCINOGENESIS

a worker exposed to radiation is not significantly more at risk than other workers. The risks to radiation workers are established by keeping records of accumulated film badge doses and accumulated internal exposures that are eventually correlated with the cause of and age at death. These data are then compared with similar data for other individuals. (20 refs)

79-3440 Implantation of Transitional Tumor Cells on the Cauterized Murine Urothelial Surface (Meeting Abstract). (Eng) Soloway, M. S. (Univ. Tennessee Center Health Sciences, Memphis, TN 38163); Masters, S. *Proc Am Assoc Cancer Res* 20: 256; 1979 (no refs)

79-3441 Assessment and Significance of the Skeletal Doses Due to ^{210}Po in Radioactive Spa Workers. (Eng) Clemente, G. F. (Laboratorio Radiotossicologia, CSN, Casaccia CNEN, C.P. 2400, 00100 Rome, Italy); Renzetti, A.; Santori, G. *Environ Res* 18(1): 120-126; 1979.

Studies of 15 workers at a spa in which patients bathe in radioactive springwater demonstrated that the urinary ^{210}Po concentrations of 10 workers were significantly higher than those of unexposed individuals. Urinary ^{210}Pb excretion was more variable, and it was higher in more recently exposed workers. (20 refs)

79-3442 Tumorigenic Hazard of Particulate α Activity in Syrian Hamster Lungs. (Eng) Anderson, E. C. (Health Div., Los Alamos Scientific Lab., Univ. California, Los Alamos, NM 87545); Holland, L. M.; Prine, J. R.; Smith, D. M. *Radiat Res* 78(1): 82-97; 1979.

Syrian hamsters were exposed to lung irradiation by three modalities that differed in degree of localization of the radiation dose and in the fraction of lung exposed. An object of these studies was to measure as directly as possible lung tumor yield as a function only of the degree of dispersion of radioactivity. This was accomplished by using microspheres that were uniform in size and radioactivity. The activity per particle and the number of particles were varied independently. Experimental conditions were chosen to determine the relative tumorigenicity of diffuse vs localized irradiation of the lung. Intratracheal instillation of ^{210}Po soln gave nearly uniform α irradiation of the entire lung, iv injection of large numbers of ZrO_2 microspheres loaded with ^{147}Pm gave whole lung exposures to low LET (linear energy transfer) radiation, and iv injection of Pu-loaded microspheres provided a series of focal α exposures with varying numbers and specific activities of particles. The Po and Pm exposures were highly

tumorigenic, whereas the Pu microspheres produced tumors only when a large fraction of the lung was exposed to large doses. Exposures of 2,000 $\text{PuO}_2\text{-ZrO}_2$ spheres per hamster, irradiating about 1% of the lung, gave no significant tumor incidence even at doses up to 118 nanocuries/g of lung tissue. It is concluded that, for a given lung burden of radioactivity, the most hazardous distribution is the most diffuse and that particulate α activity is an ineffective modality of irradiation. The importance of supplemental insults (ie, saline instillation) in determining tumor yield is shown. (35 refs)

79-3443 Morphological Changes in Rat Endocrine Organs During Chronic Internal Irradiation with ^{90}Sr . (Rus) Berezovskii, B. S. (Res. Inst. Biological Testing Chemical Compounds, Moscow, USSR). *Med Radiol (Mosk)* 24(4): 47-53; 1979.

Random-bred albino rats were given a single ip injection of ^{90}Sr (0.05 $\mu\text{Ci/kg}$) and then followed for 210 days. Only 75% of the males and 78% of the females survived to day 210 (compared with 95% and 97% of the controls). Tumors were detected in 17.3% of the male and 35.9% of the female survivors. Bone sarcomas and tumors of the hypophysis, adrenals, thyroid, testis, ovaries, mammary gland, and uterus were recorded. (9 refs)

79-3444 Effect of Small Doses of Americium-241 on Dogs and Rats. (Rus) Rudnitskaia, E. I. (No affiliation given); Moskalev, I. I. *Radiobiologiya* 19(2): 310-316; 1979.

The long term effects of exposure to a small dose of ^{241}Am were studied in dogs and random-bred albino rats. The isotope was given iv (dogs) at 0.1-7.5 $\mu\text{Ci/kg}$ or ip (rats) at 0.01-5.0 $\mu\text{Ci/kg}$. ^{241}Am was significantly more toxic for dogs than for rats; the av duration of survival of dogs inoculated with 2.5, 5.0 or 7.5 $\mu\text{Ci/kg}$ was 459, 233, and 204 days, respectively, compared with 4,778 days in controls. At 5.0 $\mu\text{Ci/kg}$, ^{241}Am caused an insignificant decrease in the av duration of survival of rats (460 days, compared with 559 days in controls). Osteosarcomas were detected in three of the four surviving dogs. The incidence of osteosarcomas in rats ranged from 4.35% at 0.01 $\mu\text{Ci/kg}$ to 12.5% at 2.5 $\mu\text{Ci/kg}$. (13 refs)

79-3445 Transfer of Actinides from the English Channel into the Southern North Sea. (Eng) Murray, C. N. (Chemistry Div., Commission European Communities, JRC Ispra Establishment, 21020 Ispra (Varese), Italy); Kautsky, H.; Eicke, H. F. *Nature* 278(5705): 617-620; 1979.

Isotopes of three actinide elements, plutonium, americium, and curium, were measured in the waters of the English Channel. On the basis of expected fallout ratios, an attempt was made to distinguish the probable source and dispersion of actinides entering the southern North Sea from the English Channel. The variations of activity concentrations in the Channel between March and October 1975 demonstrated the pulse-like nature of actinide contamination entering the North Sea. The major input of the isotopes was from a French nuclear fuel reprocessing plant at La Hague. Although plutonium water activities probably only represent <5% of the total released in low-level wastes, this fraction showed a high degree of mobility. Measurements of curium indicate that any support by americium would be minimal. It is necessary to develop methods for the analysis of the chemical forms of these elements. Actinide activities in the North Sea may be able to reflect increases in European nuclear generating and reprocessing capacities over the next few decades. (18 refs)

79-3446 Late Development of Colorectal Cancer Subsequent to Pelvic Irradiation. (Eng)

O'Connor, T. W. (Dept. Colon and Rectal Surgery, Cleveland Clinic Foundation, Cleveland, OH); Rombeau, J. L.; Levine, H. S.; Turnbull, R. B. *Dis Colon Rectum* 22(2): 123-128; 1979.

Two cases of probable radiation-induced colorectal cancer are reported. A 45-yr-old woman was treated for squamous cell carcinoma of the cervix by insertion of eight radon seeds (1.3 Ci) and by 3,000 rads of external radiation. She did well until 18 yr later, when a diagnosis of radiation proctitis and radiation stricture was made. She remained symptom-free until 12 yr after that, when she had severe tenesmus and hematochezia. The sigmoid colon was resected and a fungating, infiltrating, moderately differentiated adenocarcinoma was identified in the resected segment. A polyp proximal to the mass was identified as a tubular adenoma with mild dysplasia. A 46-yr-old woman with Stage II papillary adenocarcinoma of the endocervix received 2,800 rads of external radiation therapy followed 2 mo later by two implantations of 80 mg of radium seeds for a total of 7,680 mg-hr radiation. She remained well until 16 yr later, when a fixed pelvic mass identified as a moderately differentiated rectal adenocarcinoma was found. The fibrosis produced by the therapeutic irradiation involved the ureter and caused adhesions of the colon, uterus, and ureter. A segment of ureter was resected at colectomy, and the development of a ureterocolic fistula complicated the postoperative course. Patients with radiation-induced proctocolitis should be followed for life, and high-risk patients should have barium-enema examinations at regular intervals. The risk of radiation-associated tumors may increase in men given radiotherapy for adenocarcinoma of the prostate. (17 refs)

79-3447 Microdistribution of Thorotrast and Dose to Cellular Structures. (Eng) Kaul, A. (Freie Universitat Berlin, Klinikum Steglitz, Berlin 45, W. Germany); Foll, U.; Haase, V. A.; Palme, G.; Riedel, W.; Stolpmann, H. J. *Environ Res* 18(1): 13-22; 1979.

Thorium dioxide is distributed inhomogeneously within the tissues of Thorotrast patients. To calculate tissue and cellular dose levels in humans, experiments were conducted in female CF₁ mice and male rabbits to determine the accumulation of ThO₂ particles as a function of time after Thorotrast exposure and self-absorption of α -particles within Thorotrast aggregates of various sites. Colloidal ThO₂ was injected iv into female mice (25, 125, and 250 μ l) or administered intravascularly to male rabbits (2 ml). The animals were sacrificed between 1 and 100 or 392 days, respectively, and tissue samples of the liver and spleen were analyzed by histoautoradiography and light and electron microscopy with respect to the size distribution of the aggregates. For dose calculations, the aggregates were assumed to be spherical, and they were classified into groups within the radius range 0.045-20 μ m. Dose rate estimates were made with respect to cellular structures, cells adjacent to Thorotrast granules, and liver tissue in general, with self-absorption of α -particles being considered a function of Thorotrast particle size and duration of Thorotrast body burden. According to the results, local dose rates may vary from about 4,000 rads/yr (cell membranes) to about 30 rads/yr (mean dose rate to nuclei of liver cells). The mean dose rate to cells within the range of α -particles emitted from the aggregates will be of the order of 0.2 mrad/yr to 2 rads/yr. (6 refs)

79-3448 Evolution of Thorotrast-induced Hepatic Angiosarcomas. (Eng) Telles, N. C. (Bureau Radiological Health, Food and Drug Admin., Rockville, MD 20857); Thomas, L. B.; Popper, H.; Ishak, K. G.; Falk, H. *Environ Res* 18(1): 74-87; 1979.

Pathological findings in 25 cases of Thorotrast-induced angiosarcoma are presented. Characteristic antecedent or precursor changes similar to previously described changes present in hepatic angiosarcoma secondary to vinyl chloride, or arsenicals or of unknown etiology were found. The antecedent or precursor change consisted of areas with simultaneous activation of both the hepatocytes and sinusoidal cells and associated lesions in the sinusoidal and perisinusoidal spaces. The hepatic cell plates surrounding these areas were compressed, with subsequent development of fibrous septa at the interface between the areas of mixed hyperplasia and the areas of compression. In these multiple areas, multicentric angiosarcomas developed in close approximation to the portal tracts but not to the Thorotrast deposits. (24 refs)

- 79-3449 Thorotrast Dosimetric Study in Japan. (Eng) Kato, Y. (Nat. Inst. Radiological Sciences, Chiba, Japan); Mori, T.; Kumatori, T. *Environ Res* 18(1): 32-36; 1979.

The results of a Japanese study concerning the amounts of Thorotrast absorbed by the liver, spleen, and bone marrow of 39 exposed individuals are presented and compared with those of a similar German study. Steady-state activity ratios and the self-absorption of α particles in $^{232}\text{ThO}_2$ aggregates were determined in autopsy specimens using α - and γ -ray spectrometry. Twenty-four of the 39 individuals died of liver cancer (17 with cholangiocarcinoma, 5 with hemangioendothelioma, 2 with liver cell carcinoma). Dose absorbed by the liver in 23 of these individuals was 939 rads. The mean absorbed doses in the spleen and bone marrow in all 24 subjects were 5,760 and 3,087 rads, respectively. Causes of death in the remaining subjects were cirrhosis of the liver (6), aplastic anemia (2), and osteosarcoma, acute myeloid leukemia, erythroleukemia, lung carcinoma, sarcoma at injection site, stomach ulcer, and miliary tuberculosis (1 each). Mean absorbed doses in the liver, spleen, and bone marrow of these individuals were 893, 4,501, and 1,042 rads, respectively. (6 refs)

- 79-3450 Microdistribution of Thorotrast Conglomerates in Lymph Nodes and Radiation Exposure of Single Lymphocytes. (Eng) Steinstrasser, A. (Institut für Biophysik der Universität des Saarlandes, Boris Rajewsky-Institut, D-6650 Homburg, W. Germany); Kemmer, W.; Muth, H. *Environ Res* 18(1): 23-31; 1979.

The microdistribution of Thorotrast (TT) aggregates was studied in autopsy specimens of the lymph nodes of exposed individuals and in the lymph nodes of experimentally exposed Chinese hamsters. Some lymph nodes of exposed patients were almost free of TT, but others were not able to function because of the high TT level. The aggregates either formed a wall in the outer region of the follicle or were evenly distributed throughout the follicle. Dose rates in lymph nodes with low TT levels were similar, averaging about 210 rads/yr. Dose rates in lymph nodes with high TT levels ranged from an av of 645 rads/yr (intermediary sinus and trabeculae) to 1,352 rads/yr (marginal sinus, corresponding region of cortex) to 2,319 rads/yr (follicle wall). (16 refs)

- 79-3451 Osteosarcoma Induced by Short-lived Bone-seeking α Emitters in Mice: The Role of Age. (Eng) Luz, A. (Institut für Biologie, Gesellschaft für Strahlen- u. Umweltforschung mbH München, D-8042 Neuherberg, W. Germany); Müller, W. A.; Gossner, W.; Hug, O. *Environ Res* 18(1): 115-119; 1979.

The incidence of osteosarcoma was compared in weanling

(1-mo-old) and adult (5- to 6-mo-old) female NMRI-Neuherberg mice injected ip with isotonic solns of the α emitters ^{224}Ra and ^{227}Th . The osteosarcoma incidences in weanling and adult mice that received one injection of 25 $\mu\text{Ci/kg}$ ^{224}Ra were 18% and 9%, respectively; the incidences in mice that received one injection of 5 $\mu\text{Ci/kg}$ ^{227}Th were 42% and 19%, respectively. The incidences in animals receiving 0.28 $\mu\text{Ci/kg}$ ^{227}Th every 2 wk for 9 mo were similar, 84% and 76%, respectively. Age-corrected osteosarcoma incidences were not significantly different in the two age groups in any experiment. However, the av latent periods in the weanling mice that received a single injection of ^{224}Ra (553 days), a single injection of ^{227}Th (545 days), and long-term ^{227}Th treatment (375 days) were significantly longer than those in the adult mice (476 days, $p \leq 0.05$; 432 days, $p \leq 0.005$; and 331 days, $p \leq 0.0005$, respectively). The lower latent period in the adults may be related to age. (14 refs)

- 79-3452 Comparative Investigations on the Biokinetics of Colloidal Thorium, Zirconium, and Hafnium Dioxides in Animals. (Eng) Riedel, W. (Klinikum Steglitz, Freie Universität Berlin, Hindenburgdamm 30, D-1000 Berlin 45, W. Germany); Hirschberg, R.; Kaul, A.; Schmier, H.; Walter, U. *Environ Res* 18(1): 127-139; 1979.

The biokinetics of colloidal thorium dioxide (Thorotrast, TT), zirconium dioxide, and hafnium dioxide were compared in female Wistar rats. A thorium dioxide aquasol whose particle size distribution corresponded to that of commercial TT and dextrin-stabilized aquasols of zirconium and hafnium dioxide were administered to the rats. TT kinetics were also studied in mice, rabbits, and 1 dog. The animals received 60-600 μl of one of the aquasols, and they were sacrificed 1-100 days later. The whole-body kinetics of the thorium and hafnium dioxides were studied by single whole-body counting. Both the distribution of the colloids and the activity ratios between ^{232}Th and its daughter products were determined. The results indicate that the biological behavior of thorium dioxide colloid in animals is comparable to that in humans. With increasing amounts of the three colloids, the storage capacity of the hepatic and Kupffer cells was progressively limited. (15 refs)

- 79-3453 Thorium Dioxide and the Liver--Scintigraphic Aspects. (Eng) Oliveira, E. A. (Servico de Medicina IV, Hospital de Santa Maria, Lisbon, Portugal); Saragoca, A.; Oliveira, M. P.; Tavares, M. H.; da Silva Horta, J. *Environ Res* 18(1): 216-217; 1979.

^{131}I -rose bengal or ^{99}Tc -sulfur colloid liver scans were carried out in 24 patients who had been injected with thorium dioxide colloid (Thorotrast) 26 to 50 yr earlier. Only two

scans were considered normal. The observations were consistent with fibrosis in five and with cirrhosis in two. Of 15 patients with a scan showing single or multiple space-occupying lesions, 10 died with a clinical picture of primary liver cancer. Besides poor patient cooperation, it is felt that neither clinical examination nor biochemical and scintigraphic testing are helpful in the early diagnosis of liver malignancy in persons exposed to Thorotrast. (4 refs)

79-3454 Chromosome Radiation-induced Aberrations in Patients Injected with Thorium Dioxide.

(Eng) Teixeira-Pinto, A. A. (Laboratorio de Citogenetica, Instituto de Histologia e Embriologia, Faculdade de Medicina de Lisboa, Lisbon, Portugal); Azevedo e. Silva, M. C. *Environ Res* 18(1): 225-230; 1979.

Cytogenetic studies were carried out in 22 subjects who had been injected with thorium dioxide colloid (Thorotrast) 21-43 yr previously. No significant differences in the number of abnormal cells or chromosome breaks were found when nine patients who received <24 ml of Thorotrast intraarterially and four patients who received >24 ml of Thorotrast intraarterially were compared. The percentages of abnormal cells and breaks in the 13 intraarterially injected patients were 8.78% and 15.58%, respectively. In the seven patients who had received only 2 ml of Thorotrast for perinasal sinus visualization, the incidences of acentrics, dicentrics, and breaks were 5.34%, 0.89%, and 7.12%. The percentages of acentrics and dicentrics in the systemically injected patients, who received 7-36 ml Thorotrast, were 8.02% and 3.58%, respectively. (12 refs)

79-3455 Movement of Thorotrast Aggregates in the Bone Marrow.

(Eng) da Silva Horta, J. (Dept. Pathology, Faculty Medicine, Lisbon, Portugal); Moura Nunes, J. *Environ Res* 18(1): 184-191; 1979.

Morphologic and autoradiographic studies of the distribution of thorium dioxide colloid (Thorotrast, TT) in autopsy specimens of bone from 23 exposed individuals demonstrated that the greatest amounts accumulated in or near the trabeculae. There was little accumulation in the periosteum and in the channels and spaces of Havers. TT aggregates were much more abundant in active bone marrow than in adipose marrow. These and further observations suggest that TT aggregates are attracted to the endosteal surfaces of bone. (11 refs)

79-3456 Chromosome Aberrations as a Biological Dosimeter in Thorotrast Patients: Dosimetric Problems.

(Eng) Kemmer, W. (Bundesministerium des Innern, D-5300 Bonn 1, W. Germany); Steinstrasser, A.; Muth, H. *Environ Res* 18(1): 178-183; 1979.

Cytogenetic studies of lymphocytes from 68 Thorotrast-exposed subjects showed dicentric chromosome aberrations in all subjects. However, there was no clear dose-response relationship between chromosome aberration rate and calculated whole-body Thorotrast exposure or between chromosome aberration rate and estimated dose absorbed by the reticuloendothelial system. (11 refs)

79-3457 Pathological Changes of Lymph Nodes in Thorotrast Patients. Pathoanatomical, Autoradiographical, and Quantitative Investigations.

(Eng) Wegener, K. (Pathological Inst., Municipal Hosp. Ludwigshafen, Bremserstrasse 79, 6700 Ludwigshafen/Rhein, W. Germany); Wesch, H. *Environ Res* 18(1): 245-255; 1979.

Pathological, autoradiographic, and quantitative studies of postmortem organ specimens of 38 patients with thorotrastosis demonstrated that the highest ^{232}Th concentrations were in the lymph nodes of the liver hilus, those in the area behind the pancreas, and those around the hilus of the spleen. The latency period, ie, the time between Thorotrast injection and death, ranged from 24 to 38 yr. (35 refs)

79-3458 Biological Activity In Vitro of Chrysotile Compared to Its Quarried Parent Rock (Platy Serpentine).

(Eng) Frank, A. L. (Environmental Sciences Lab., Dept. Community Medicine, Mount Sinai Sch. Medicine, New York, NY 10029); Rohl, A. N.; Wade, M. J.; Lipkin, L. E. *J Environ Pathol and Toxicol* 2(4): 1041-1046; 1979.

The biological activities of the fibrous serpentine mineral chrysotile, asbestos and the platy serpentines quarried at Rockville, Maryland, were evaluated via an in vitro bioassay using the malignant mouse macrophagelike cell line P338D₁. Crushed stone from the quarry is used for roads, playgrounds, and other surfaces. Air samples taken in the vicinity of roads paved with the stone showed that chrysotile concentrations were approx 1,000 times greater than those found in typical urban areas of the US. The chrysotile (100 $\mu\text{g}/\text{ml}$) was cytotoxic at 72 hr, whereas the ground rock sample (platy serpentine) had no effect on cell growth. Although there are at present no scientific data to relate cytotoxicity to carcinogenicity directly, the fact that there is significant biological activity in the extracted chrysotile from the quarried rock brings the Rockville Quarry problem into sharper focus. (8 refs)

79-3459 Studies on In Vitro Asbestos-Cell Interaction.

(Eng) Wade, M. J. (NCI, Park Bldg. Rm. 417, 9000 Rockville Pike, Bethesda, MD 20014); Lipkin, L. E.;

PHYSICAL CARCINOGENESIS

Frank, A. L. *J Environ Pathol and Toxicol* 2(4): 1029-1039; 1979.

The effects of filtration, prior leaching, and exposure time to the cytotoxic effects of amosite and chrysotile B asbestos on malignant mouse macrophagelike (P388D₁) cells and human lung (WI-38) cells were studied. Unfiltered chrysotile (100 µg/ml) was cytotoxic to P388D₁ cells, whereas the chrysotile filtrate had no such effect. Unfiltered amosite also caused cytotoxicity, but not the amosite filtrate. Cytotoxicity correlated well with duration of exposure; after 12-24 hr, no additional cytotoxic effect was noted. However, all the asbestos could not be removed by washing, and some residual asbestos was present. Phagocytosis of the asbestos did not block the progression of P388D₁ cells through the cell cycle, unless fibers were present in sufficient concentration or positioned to cause irreversible cell damage. WI-38 cells exposed to amosite showed little morphological change, but cells exposed to chrysotile appeared to elongate and contract, becoming narrower and more fibrous with the appearance of intercellular spaces. (17 refs)

79-3460 Determination of Microgram Quantities of Asbestos by X-Ray Diffraction: Chrysotile in Thin Dust Layers of Matrix Material. (Eng) Lange, B. A. (Center Disease Control, Natl. Inst. Occupational Safety and Health, US Dept. Health, Education, and Welfare, 4676 Columbia Parkway, Cincinnati, OH 45226); Haartz, J. C. *Anal Chem* 51(4): 520-525; 1979.

A precise, accurate, and rapid x-ray diffraction method was developed to determine microgram quantities of chrysotile (serpentine asbestos). The method can measure microgram amounts of either pure chrysotile or small quantities of chrysotile (typically, 1%-10% by wt) in the presence of large amounts of matrix material. Detection limits as low as 2 µg/cm² (on a filter) are cited. In the development of this method, phase analysis procedures, method sample preparation, and a technique for x-ray absorption corrections were evaluated. The primary drawback of the method is interference by minerals such as antigorite, lizardite, the kaolinities, and, possibly, chlorite. Sample pretreatment and x-ray line profile analysis may reduce the adverse effects of interferences. (28 refs)

79-3480 Late Transcription and Simultaneous Replication of Simian Adenovirus 7 DNA as Revealed by Spreading Lytically Infected Cell Cultures. (Eng) Matsuguchi, M. (Dept. Microbiology, Faculty Medicine, Kyushu Univ., Fukuoka 812, Japan); Puvion-Dutilleul, F.; Moyne, G. *J Gen Virol* 42(3): 443-456; 1979.

Miller's technique of spreading transcription complexes was used to study virus replication and transcription in simian adenovirus 7 (SA7)-infected green monkey kidney cells. Electron micrographs demonstrated that transcription and replication occurred both separately and simultaneously on the same adenovirus DNA molecule late in the lytic cycle. Virus DNA from infected cells was identified by the presence of molecular species not observed in control cells: duplex DNA of limited length, almost smooth, carrying replication forks and ribonucleoprotein fibrils. Each one of these features was sufficient to characterize a novel kind of deoxyribonucleoprotein morphologically. The observation of numerous replication forks demonstrated that the single-stranded molecule remains bound to the DNA duplex during the spreading procedure. Three main forms of replication complexes were distinguished: Y-shaped replication forks, linear molecules in transition from single- to double-strandedness, and linear molecules that were entirely single- or double-stranded. There were pronounced discrepancies between the present measurements of the SA7 genome length and theoretical values estimated from the mol wt of a linear, double-stranded molecule. This may be explained by spreading or artifactual breaks of the virus DNA molecules, but a compaction of the DNA by proteins cannot be excluded. No differences in morphology between transcription of adenovirus DNA and transcription of non-nucleolar mammalian cell DNA, as studied by Miller's technique, were observed. (31 refs)

79-3485 Isolation and Characterization of BK Virus-transformed Rat and Mouse Cells. (Eng) Seehafer, J. (Dept. Biochemistry, Univ. Alberta, Edmonton, Alberta T6G 2H7, Canada); Downer, D. N.; Salmi, A.; Colter, J. S. *J Gen Virol* 42(3): 567-578; 1979.

Four groups of BK virus (BKV)-transformed rat embryo fibroblast (RE) and mouse kidney (MK) cells were isolated and characterized. They consisted of (1) 7 RE lines transformed with a BKV pool containing a high proportion of defective virions, and (2) 16 RE, (3) 14 BALB/c-MK, and (4) 2 Swiss ICR-MK lines transformed (at different input multiplicities), with a pool of BKV free of defective virions. None of the lines produced BKV, all contained BKV tumor antigen, and all grew to higher saturation densities and had higher plating efficiencies than the corresponding control cells. Cells of the RE lines transformed with the BKV pool containing defective virions formed colonies in soft agar and produced tumors in irradiated weanling rats, but cells of the RE lines transformed with the defective virion-free pool did neither. Cells of the BALB/c-MK lines, but not of the ICR-MK lines, were tumorigenic, although cells of both groups formed colonies in soft agar. In general, lines transformed at higher multiplicities expressed the biological properties associated with transformation more strongly than those transformed at lower multiplicities. (12 refs)

PATHOGENESIS

79-3531 A Histopathological Study of Lymphoid Tissue Reaction to Metastatic Nasopharyngeal Carcinoma in Nude Mice. (Eng) Chen, H. C. (Dept. Immunology, Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 108, Japan); Kawamura, A.; Murata, M.; Hamajima, K.; Osono, M.; Suzuki, K.; Sudo, K. *IARC Sci Publ* 20: 65-84; 1978.

Lymphoid tissue reactions to metastatic nasopharyngeal carcinoma (NPC) were studied in nude mice. Successful transplants were obtained with 2/7 human NPC cultured cell lines, NPC-204 and NPC-501. Lymphatic metastases occurred during generations 11-15, and 24-30 with NPC-204 and during generations 9-14 with NPC-501. Only the regional nodes were involved. During the first few passages (prometastatic phase), large numbers of wandering macrophages appeared in the dilated medullary sinuses in response to the tumors. As the number of wandering macrophages in the medullary sinuses gradually decreased, diffuse hyperplasia of the lymphocytes occurred in regional lymph nodes. The spleen underwent extensive change, as manifested by the collapse of the splenic cords and the formation of septa studded with granulomas. These changes occurred in the absence of tumor cells, and they are regarded as a defense reaction of the reticuloendothelial system. Neighboring lymph nodes were also often studded with epithelioid cell granulomas, formed by the aggregation of macrophages around nuclear debris in the subcortical areas. It is assumed that the clumps of debris are the remnants of metastatic cancer cells killed by macrophages or sensitized lymphocytes. It would appear, therefore, that macrophages can replace T lymphocytes in killing tumor cells and in protecting the lymph nodes from the spread of metastases. (36 refs)

79-3532 Histopathological Types of Nasopharyngeal Carcinoma in a Low-Risk Area: Japan. (Eng) Sugano, H. (Dept. Pathology, Cancer Inst., 1-37 Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Sakamoto, G.; Sawaki, S.; Hirayama, T. *IARC Sci Publ* 20: 27-39; 1978.

Biopsy material from 816 Japanese patients with nasopharyngeal carcinoma (NPC) was examined histopathologically. A comparative study of NPC among the Taiwanese and an immunoserological study were also performed. Malignant nasopharyngeal tumors in Japanese patients were characterized by a predominance of squamous cell carcinoma, especially of the poorly differentiated type, and a relatively high frequency of malignant

lymphoma. Of 731 NPC cases, 635 were poorly differentiated and 96 were well-differentiated squamous cell carcinomas. The former included 45.8% spindle-polygonal cell carcinomas, 26.6% transitional cell carcinomas, and 14.3% lymphoepitheliomas. Well-differentiated carcinomas were infrequent in both the Japanese and Taiwanese, especially in the latter. Poorly differentiated carcinomas, especially transitional cell carcinomas and lymphoepitheliomas, were more frequent among the Taiwanese. In 84 Japanese NPC patients tested, the anti-Epstein Barr viral capsid antigen (VCA) antibody titer was very high in patients with lymphoepitheliomas, 80% of whom showed positive reactions. Positive rates for other types ranged from 33% (well-differentiated carcinoma) to 47% (spindle-polygonal cell and transitional cell carcinomas). However, in a similar study of 205 Taiwanese NPC patients, anti-VCA antibody titers and positivity rates were almost the same in all subgroups of poorly differentiated carcinoma. The serological results obtained with the Japanese study suggest that EBV genomes in NPC cells vary with the grade of differentiation of NPC. (18 refs)

79-3533 Paraneoplastic Acrokeratosis. (Ger) Bazex, A. (Clinique Dermatologique, Hopital de Purpan, F-31000 Toulouse, France). *Hautarzt* 30(3): 119-123; 1979.

The general clinical aspects of paraneoplastic acrokeratosis (PA) are described. PA is a distinctive dermatosis occurring exclusively in patients with primary malignant tumors of the upper respiratory and digestive tracts and in those with cervical and mediastinal metastases. The primary tumor is usually a spindle cell carcinoma, at times an anaplastic carcinoma, and, on rare occasions, an adenocarcinoma. PA can precede the symptoms of tumor. PA is characterized by centripetally spreading erythematous, squamous, and hyperkeratotic plaques that heal only after removal of the carcinoma. PA may be caused by an allergic or toxic skin reaction to substances produced by the tumor cells. (37 refs)

79-3534 Bazex-Dupre Paraneoplastic Acrokeratosis. (Fre) Jeune, R. (Clinique Dermatologique, Hopital E.-Herriot, F 68374 Lyon Cedex 2, France); Thivolet, J.; Chabbeau, G.; Descos, L. *Lyon Med* 241(4): 235-237; 1979.

Bezex-Dupre paraneoplastic acrokeratosis (PA) was

diagnosed in two men aged 65 and 66 yr. An epithelioma was found in the piriform sinus of one patient, a poorly differentiated malpighian epithelioma in the thymus of the other. Bazex-Dupre PA is often concomitant with and a precursor of cancer of the digestive and respiratory tracts. (4 refs)

- 79-3535 Dysphagia.** (Eng) Castell, D. O. (Digestive Diseases Branch, Internal Medicine Service, Natl. Naval Medical Center, Bethesda, MD 20014); Knuff, T. E.; Brown, F. C.; Gerhardt, D.C.; Burns, T. W.; Gaskins, R. D. *Gastroenterology* 76(5, part 1): 1015-1024; 1979.

The case history of a patient with long-standing gastroesophageal reflux resulting in peptic stricture and dysphagia is presented. Metaplastic changes typical of Barrett's esophagus occurred in the esophageal mucosa, with the subsequent development of midesophageal adenocarcinoma (mid-EAC). The patient had three recurrences of dysphagia. The third recurrence also affected the ingestion of liquids, which is unusual for a peptic stricture. Coupled with a 33-lb wt loss, it suggested the possibility of a malignant process. Literature review indicates that stricture formation occurs frequently in the setting of a columnar-lined lower esophagus. Twenty-eight of 304 patients with a columnar-lined lower esophagus developed EA. Multiple biopsies of the esophagus at the time of previous stricture formation might have revealed a columnar-lined lower esophagus, and a closer surveillance program might have detected the EA in an earlier stage. Patients with Barrett's esophagus also have a propensity to develop EA. Esophageal metaplasia of the type characteristic of Barrett's esophagus is recognized as a premalignant condition for EA. Esophageal carcinoma is occurring with increasing frequency in the American population, and it has an extremely grave prognosis. (49 refs)

- 79-3536 Malignant Melanoma of the Small Intestine Arising from a Regressive Skin Lesion.** (Fre) Saby, R. (Services de chirurgie, Hopital de Libourne, 33500 Libourne, France); Chate, M.; Hypousteguy, D.; Baste, J. C. *Chirurgie* 104(10): 913-920; 1978.

A large malignant melanoma of the small intestine was removed from a 51-yr-old man undergoing laparotomy for acute abdomen. Mesenteric lymph node metastases were also removed. The patient is in good condition 4 yr after surgery and chemotherapy. He had had a small brownish tumor under the right ear that regressed spontaneously within a few months 3 yr prior to discovery of the melanoma. Biopsy from the tumor site suggested a regressed nevus. Thus, the intestinal melanoma may have been a primary tumor or one that was secondary to the skin melanoma. (no refs)

- 79-3537 Recurrent Stupor, Diabetes, Hypothyroidism and Liver Disease in an Elderly Woman.** (Eng) Axelrod, L. (Massachusetts General Hosp., Boston, MA); Vickery, A. L. *N Engl J Med* 300(17): 969-976; 1979.

The case report of a patient with idiopathic hemochromatosis plus hepatic failure, hepatic encephalopathy, diabetes mellitus, cardiomyopathy, and, possibly, pituitary involvement manifested as hypothyroidism is presented. The patient was a 71-yr-old woman with a 10-yr history of recurrent confusion, stupor, and coma. At autopsy, micronodular cirrhosis and hepatocellular carcinoma were evident. (30 refs)

- 79-3538 Hypothyroidism Significantly Prolongs the Survival of Rats Bearing Morris Hepatoma #44 (Meeting Abstract).** (Eng) Mishkin, S. (Dept. Medicine, Royal Victoria Hosp., McGill Univ. Clinic, Montreal H3A 1A1, Canada); Huang, S. N.; Morris, H. P.; Yalovsky, M.; Murthy, P. V. *Proc Am Assoc Cancer Res* 20: 74; 1979 (1 ref)

- 79-3539 Nephroblastoma of the Renal Pelvis Mixed with Sarcoma Botryoides.** (Ger) Heising, J. (Urologische Universitätsklinik, Universität Köln, D-5000 Köln 41, W. Germany); Engelking, R.; Bohr, M.; Lennartz, K. J.; Fuhrmann, U.; Huls, W.; Rottinger, E. M. *Urologe [A]* 18(2): 68-72; 1979.

Nephroblastoma of the renal pelvis with a sarcoma botryoides component was found in a 4-yr-old girl. The histogenesis of this dysontogenetic tumor is probably due to the altered growth and differentiation of the metanephrogenic blastoma and, partly, of the ureteral bud. (10 refs)

- 79-3540 Fibrosarcoma in a Renal Oncocytoma.** (Ger) Blessing, M. H. (Pathologisches Institut der Krankenhauser der Stadt Köln, Ostmerheimer Strasse 200, D-5000 Cologne 91, W. Germany); Burkert, E.; Lehmann, H. D. *Urologe [A]* 18(2): 99-101; 1979.

A tumor of the left kidney was found in a 69-yr-old man. He agreed to undergo surgery 3.5 yr later. A large tumor consisting of mixed oncocytic adenoma and fibrosarcoma was found. The malignant tumor is believed to have originated from necrotic parts of the benign adenoma as a result of excessive regeneration. (15 refs)

- 79-3541 Malignant Transformation of Aneurysmal Bone Cysts in Childhood.** (Ger) Angerpoint-

PATHOGENESIS

ner, T. (Kinderchirurgische Klinik, Dr. v. Haunersches Kinderspital, Lindwurmstrasse 4, 8000 Munich 2, W. Germany); Engert, J.; Konrad, E.; Meister, P. *Z Kinderchir* 26(2): 143-149; 1979.

An aneurysmal bone cyst of the right tibia was diagnosed in a 3.5-yr-old girl in connection with a pathological fracture. Even though the patient was not irradiated, clinical and histological signs of malignancy increased rapidly, forcing amputation 8 mo later. Polynuclear giant cells, spindle cells, and increased cellular atypia were seen. The tumor was diagnosed as a poorly differentiated osteosarcoma. The patient received chemotherapy after the amputation, and she is in good health 4 yr later. The findings suggest there may be a malignant aneurysmal bone cyst with special biological properties. (26 refs)

79-3542 Medullary Carcinoma of the Thyroid: Study of a Kindred. (Fre) Allannic, H. (Service de Clinique Therapeutique C, Hopital Pontchaillou, F 35000 Rennes, France); Lorcy, Y.; Cornec, A.; Le Marec, B.; Calmettes, C. *Ann Endocrinol (Paris)* 40(1): 61-62; 1979.

Two proved and two probable cases of medullary carcinoma of the thyroid (MCT) without pheochromocytoma, hyperparathyroidism, or Cushing's disease were found in one family. Four other members suffered from intestinal occlusion in childhood. The findings indicate that MCT is transmitted as an autosomal dominant trait with a high degree of penetrance. (2 refs)

79-3543 Immunochemical Biological Markers and Hereditary Cancer Risk. (Eng) Guirgis, H. A. (Dept. Community and Environmental Medicine, Univ. California Sch. Medicine, Irvine, CA 92717); Lynch, H. T.; Harris, R. E.; Vandevoorde, J. P. *Scand J Immunol [Suppl]* 8(8): 647-652; 1978.

Several putative biological markers of cancer risk (carcinoembryonic antigen, α -fetoprotein, aryl hydrocarbon hydroxylase, percentage of T and B lymphocytes and IgA, IgM, and IgG) were studied in relatives at high genetic risk for cancer within a kindred manifesting the cancer family syndrome. Thirteen of the 19 individuals studied were unaffected progeny of affected direct genetic line parents. The remaining six individuals had cancer. A predictive index of cancer susceptibility that incorporates five of the putative markers was derived. The number of individuals manifesting a significant index score was compared with the number expected to carry the cancer-predisposing gene among the 13 unaffected progeny of affected parents. The observed number of aberrant index scores agreed precisely with that expected based upon gene segregation and the age distribution of the sample. The proposed index appears to provide predictability of cancer risk status in accord with

mathematical expectations for a simple genetic model. (16 refs)

79-3549 Cerebromeningeal Involvement in Acute Myeloblastic Leukemia and Myeloproliferative Syndromes. Cytological, Histological and Clinical Study of 62 Cases. (Fre) Henin, D. (Service Central d'Anatomie et de Cytologie Pathologiques, Hopital Beaujon, 100 Boulevard du General Leclerc, F 92118 Clichy, France); Slabodsky-Brousse, N.; Renoux, M.; Dhermy, D.; Bernard, J. F. *Nouv Presse Med* 8(10): 751-754; 1979.

Forty-six patients (30 men, 16 women, av age 52.9 yr) with

acute myeloblastic leukemia (AML) and 16 patients (10 men and 6 women, av age 57.6 yr) with myeloproliferative syndromes (MPS) were examined for cerebrospinal involvement (CMI). CMI was proved anatomically in 28/62 patients, but only 18/28 patients had neurological signs; however, patients without CMI had neurological signs. Examination of the cerebrospinal fluid of 22 AML patients and 4 MPS patients revealed blastic infiltration in 15. Autopsy examination of 30 AML patients and 15 MPS patients revealed CMI in 12 and 6 patients, respectively. The arachnoidea was involved in 18 cases, the dura mater in 10, and the cerebral parenchyma in 5. Intracerebral hemorrhages were found at autopsy in 19/27 patients without CMI. (20 refs)

79-3550 Increased In Vitro Radiosensitivity in Some Skin Fibroblast Cultures From a Family with Multiple Cases of Acute Myelogenous Leukemia (AML) (Meeting Abstract). (Eng) Bech-Hansen, N. T. (Atomic Energy Canada Limited, Chalk River, Ontario, K0J 1J0, Canada); Sell, B. M.; Anderson, A. K.; Mulvihill, J. J. *Proc Am Assoc Cancer Res* 20: 78; 1979 (2 refs)

79-3551 Non-random Clonal Evolution in 45 Cases of Chronic Myeloid Leukemia. (Eng) Stoll, C. (Institut de Puericulture, 23 rue de la Porte de l'Hopital, 67000 Strasbourg, France); Oberling, F. *Leuk Res* 3(2): 61-66; 1979.

Chromosome analyses were made of the blood and bone marrow of 52 chronic myeloid leukemia (CML) patients during blastic crisis. Most of the analyses were performed with the use of the RHG-banding technique (analysis of R bands by heat treatment and Giemsa staining). Forty-five patients had other chromosomal aberrations in addition to the Philadelphia chromosome (Ph¹). A second Ph¹ chromosome was found in 28 patients. An additional long arm of chromosome 17 [trisomy 17, or i(17q)] was seen in 29 patients and a trisomy 8 in 13. These three main aberrations occurred alone or together in the same cell. Thirteen patients had two Ph¹ chromosomes and trisomy 17q without trisomy 8. The results indicate that chromosome involvement in the development of CML is nonrandom. Karyotypic evolution usually proceeded by the addition of chromosomes. Seventeen patients had hyperdiploidy, 1 hypodiploidy, and 27 pseudodiploidy. A clonal evolution could be demonstrated in all 45 patients with chromosome changes in addition to Ph¹. Clonal evolution was simple in 32 patients, following a linear pathway; it was the result of successive mitotic nondisjunctions. In 13 patients, clonal evolution was more complex, following a divergent pathway and resulting in several subpopulations. (17 refs)

79-3552 Follicular Mucinosis (Lymphoma) Occurring on the Head and Neck. (Eng) Wilkinson, J. D.

(Slade Hosp., Headington, Oxford OX3 7JH, England); Dawber, R. P.; Ryan, T. J.; Millard, P. R. *J R Soc Med* 72(4): 281-282; 1979.

The case report of a 71-yr-old woman with lymphoma associated with follicular mucinosis of the head and neck is presented. A scaly erythematous rash on the face was progressively replaced by waxy indurated areas with gelatinous plaques, prominent cysts, and follicular plugging. The initial biopsy showed spongiotic vesicles and a patchy infiltrate of mononuclear cells with some pleomorphic forms. A biopsy 5 mo later demonstrated a substantial mononuclear cell infiltrate surrounding the follicles and extending deep into the dermis. Among these cells were pleomorphic atypical forms. (3 refs)

79-3555 Skin Metastases of an Ovarian Carcinoma Mimicking Erythema Annulare. (Ger) Bernecker, H. A. (Dermatologische und Allergologische Abteilung, Städtisches Krankenhaus München-Schwabing, Kölner Platz 1, D-8000 Munich 40, W. Germany); Bachmann, W. *Hautarzt* 30(3): 164-165; 1979.

Erythema annulare was found in a 60-yr-old woman 2 mo after the removal of a large ovarian cystoma, at which time tumor cells were found in the ascitic fluid. Biopsy revealed carcinoma cells in the erythema annulare, which was thus a metastasis of an undetected carcinomatous component of the cystoma. (5 refs)

79-3556 Turner's Syndrome: A Six-Year Experience. (Eng) Stenchever, M. A. (Dept. Obstetrics and Gynecology, Univ. Washington Sch. Medicine, Seattle, WA 98195); Parks, K. J.; Stenchever, M. R. *Trans Am Gynecol Soc* 101: 167-172; 1978.

A 6-yr experience of one genetics laboratory with patients

PATHOGENESIS

referred for evaluation of possible Turner's syndrome is reported. One of the 13 individuals with karyotypic evidence of the syndrome developed a well-differentiated endometrial adenocarcinoma while on estrogen replacement therapy. This patient, a 27-yr-old woman, had been treated for 14 yr with diethylstilbestrol (25 days/mo). (19 refs)

MISCELLANEOUS

- 79-3586 Polyamine Content and Release during the Proliferation of Burkitt's Lymphoma Cells In Vitro.** (Eng) Woo, K. B. (Biological Markers Lab., NCI Frederick Cancer Res. Center, Frederick, MD 21701); Perini, F.; Sadow, J.; Sullivan, C.; Funkhouser, W. *Cancer Res* 39(7): 2429-2435; 1979.

The cellular content and excretion of polyamines in relation to the cell cycle and proliferation kinetics of Burkitt's lymphoma cells in vitro were investigated. Quantitative relationships were established between the cellular content of polyamines and the growth kinetic parameters, including specific growth rate, labeling index, and cell viability. The intracellular content of putrescine, spermidine, and spermine correlated significantly with the specific growth rate, suggesting that all the polyamines actively participate in the process of Burkitt's lymphoma cell proliferation. A negative correlation was found between the labeling index and the intracellular content of putrescine ($r = -0.893$); a positive correlation was observed between the labeling index and the ratios of spermidine to putrescine (0.888) and spermine to putrescine (0.855). In addition, the extracellular content of putrescine showed a positive correlation with the labeling index (0.613). The percentage of dead cells determined by trypan blue exclusion exhibited a high positive correlation with the intracellular content of putrescine (0.912). Examination of the distribution pattern of polyamines with respect to the fraction of cells in each cell cycle stage during a 10-day growth period revealed that the accumulation of cells in G_2 was associated with a reduction of intracellular levels of spermidine and spermine. In cultures synchronized by double thymidine blockade, maximal levels of intracellular spermidine and spermine occurred in S phase. Intracellular putrescine levels were lowest when the DNA content was lowest in early and mid-S phase, and they were highest when the DNA content was highest in late S and early $G_2 + M$. (39 refs)

- 79-3587 Differences in the Peripheries of Walker Cancer Cells Growing in Different Sites in the Rat.** (Eng) Weiss, L. (Dept. Environmental Pathology, Roswell Park Memorial Inst., Buffalo, NY 14263); Harlos, J. P. *Cancer Res* 39(7, part 1): 2481-2485; 1979.

Walker 265 carcinosarcoma cells growing in the ascitic form and following direct injection of 10^6 cells in the livers or in sc sites in Sprague-Dawley rats had significantly higher anodic electrophoretic mobilities than did cells derived from the same source but growing in kidneys and

spleens. Following incubation with neuraminidase, the cancer cells from the kidneys and spleen lost significantly less net surface negativity than did cells growing in the other three sites. These kidney- and spleen-associated differences were not demonstrably due to preexisting, electrokinetic subpopulations of cancer cells within the original ascites tumor; they were maintained on organ-to-organ passage and were reversed on reconversion of the tumors to ascitic form. The differences between primary cancers and their metastases are conceivably due to site-induced modulation as distinct from preexisting metastatic subpopulations. There is evidence that cancer cells in some primary tumors are different from those in their metastases, at least in some organs. The possibilities arise that specific organs are selectively seeded by preexisting subpopulations of cancer cells from within the primary tumor or that the seeding is random. In either case, cells in metastases are different because they are located in specific metastatic sites. (38 refs)

- 79-3588 Plasminogen Activation Transforms the Morphology of Quiescent 3T3 Cell Monolayers and Initiates Growth.** (Eng) Whur, P. (Marie Curie Memorial Foundation, Oxted, Surrey, England); Silcox, J. J.; Boston, J. A.; Williams, D. C. *Br J Cancer* 39(6): 718-730; 1979.

Attempts were made to induce transformation-like morphology and growth in confluent quiescent 3T3 cells in tissue culture by activating plasminogen (PM) via the addition of urokinase (UK) and PM or PM-containing acid-treated serum, or plasmin. Cells in medium supplemented with UK alone formed well-ordered confluent monolayers. When UK and PM were both added to PM-free acid-treated horse serum, there was cell elongation and multi-layering followed by the formation of thick cords of cells which left large areas of the growth surface almost devoid of cells. These changes were associated with growth to significantly higher densities than those of the controls. Similar but more rapid growth was seen when acid-treated horse serum was used instead of PM supplementation, and similar but less marked changes were seen in the presence of plasmin. There was a partial reversal of the supplement-induced disruption when the cells were returned to medium containing acid-treated PM-free serum. The data indicate that well-ordered monolayer morphology and quiescence in 3T3 cells at confluence are dependent on the absence of PM activation. (54 refs)

79-3589 Biochemical and Genetic Evidence for Two Extracellular Adenosine 3':5'-Monophosphate Phosphodiesterases in *Dictyostelium purpureum*. (Eng) Tsang, A. S. (Imperial Cancer Res. Fund, Mill Hill Labs., Burtonhole Lane, London NW 1AD, England); Coukell, M. B. *Eur J Biochem* 95(2): 407-417; 1979.

Two extracellular AMP phosphodiesterases (PDE-1 and PDE-2) were purified from growth media of cultures of the cellular slime mold *Dictyostelium purpureum*. Both enzymes have a broad pH optimum of 7.5-8.6, but they differ in mol wt, stability, kinetic behavior, and sensitivity to inactivation by the PDE inhibitor of *D. discoideum*. The polypeptides associated with the two enzyme activities were identified on two-dimensional gels. Under these conditions, the polypeptides associated with PDE-1 activity had a mol wt of 60,000 and an apparent isoelectric point of pH 8.5. Two polypeptides (mol wts 50,000 and 48,000) were associated with PDE-2 activity. These two polypeptides had the same isoelectric point of about pH 7.5 and very similar peptide maps. With Coomassie blue stain, the ratio of the 50,000-mol wt polypeptide to the 48,000-mol wt polypeptide was 3:1; the same polypeptides appeared to be present in a 6:1 ratio when they were stained with PAS reagent. These results suggest that the major difference between the 50,000- and 48,000-mol wt polypeptides is in the size of their carbohydrate moieties. Several developmental mutants were isolated that synthesize the PDE's abnormally. Results of an examination of enzyme production in two of these mutants provided further evidence for the existence of two extracellular AMP PDE's in *D. purpureum*. In addition, these results revealed that PDE-1 is synthesized during vegetative growth, whereas PDE-2 is synthesized toward the end of the growth phase and during early development. (40 refs)

79-3592 Morphological Markers of Oncogenic Transformation in Respiratory Tract Epithelial Cells. (Eng) Heckman, C. A. (Biology Div., Oak

Ridge Natl. Lab., Oak Ridge, TN 37830); Olson, A. C. *Cancer Res* 39(7): 2390-2399; 1979.

Changes in cell shape and microvillar density accompanying oncogenic transformation were studied in rat respiratory tract epithelial cells. Two cell lines that became tumorigenic during in vitro culture (1000 W and 165 S) were studied. In relatively late passages, but not in early passages, the lines produced keratinizing squamous cell carcinomas when tested in syngeneic hosts. Small colonies, predominantly of clonal origin, were obtained early and late after initiation of the lines in in vitro culture. Scanning electron microscopic studies showed that preoncogenic and oncogenic populations differed with respect to the shapes of cells within colonies. Differences in cell shape were analyzed further by estimating the height and the ratio of length to width for 20 cell samples from each colony. Each cell was assigned to one of nine classes of cell shape. The frequency with which spindle-shaped cells were observed in colonies increased threefold with oncogenic transformation of the 1000 W and 165 S lines. The frequency did not increase during in vitro culture of a third highly oncogenic cell line, BP 3-0. The frequency of the spindle-shaped cells in the 1000 W line was not decreased by in vivo growth and rederivation. In fact, a tumor-derived subline, (1000 WT), exhibited a fivefold greater frequency of such cells than an early passage of the 1000 W line. The number of colonies with this cell shape also increased fivefold and came to include nearly one-half of the colonies analyzed. Therefore, expression of the spindle shape became prevalent in clonal subpopulations. In early passages of the 1000 W and 165 S lines, most spindle-shaped cells were found at the edges of colonies. This suggested that the spindle shape was assumed in response to forces generated during colony expansion. In general, the 1000 W line, which was more oncogenic than the 165 S line, also showed more pronounced morphological alterations. The prevalence of ruffles was correlated with oncogenicity in the 1000 W line. However, the cell lines differed with respect to the density of microvilli at the cell surface, and this feature did not correlate with oncogenicity. The results indicate that the transformation of epithelial cells is accompanied by cytoskeletal and/or adhesive alterations. (33 refs)

79-3593 Effect of Different Nutrient Media on Diploidy and the Detection of Spontaneous Transformation of Rat Embryo Connective Tissue Cells. (Rus) Eroshkina, A. M. (Cancer Res. Center, Moscow, USSR). *Vopr Onkol* 25(4): 78; 1979.

The effect of various nutrient media on the detection of spontaneous transformation of cells in continuous cultures was studied. Cultures of rat embryo connective tissue were grown in five media. The cultured cells were systematically injected into newborn rats, and tumor development at the injection site indicated that malignant transformation had occurred. Regardless of the type of medium, malignant

transformation was detected within 8-15 mo of culturing. The addition of amniotic fluid or embryonal extract inhibited malignant transformation significantly (1.5- to 2-fold). The culture remained diploid for 6-15 mo of cultivation in media containing amniotic fluid or embryonal extract, 12-20 mo of cultivation in medium 199, 2.5-3 yr of cultivation in Eagle's medium, and for 4-4.5 yr of cultivation in double Eagle's medium. These findings indicate that chromosome aberrations cannot be regarded as a sign of malignant transformation. (no refs)

79-3598 Comparative Aspects of Nuclear Proteins and Nuclear Composition of Cultivated Embryonic, Neonatal and Neoplastic Rat Brain Cells of Glial Origin. (Eng) Chilina, A. R. (Dept. Environmental Practice, Univ. Tennessee, Knoxville, TN 37901); Chang, M.; Ives, D. H.; Koestner, A. *Res Commun Chem Pathol Pharmacol* 24(2): 289-305; 1979.

The chemical composition of nuclei isolated from embryonic and neonatal cultured rat brain glial cells and from

cultured neoplastic rat brain glioma (T-9) cells were studied and the results compared with those obtained from HeLa S-3 cell nuclei. The T-9 cell nuclei contained significantly more total and soluble protein than the normal rat brain cell nuclei, and nuclear RNA was much more abundant in the T-9 than in the untransformed nuclei. The embryonic brain cell nuclei contained substantially more nuclear RNA than the neonatal glial cell nuclei. Equal quantities of histones were found in the normal and transformed nuclei, but the T-9 and HeLa nuclei contained more acid-soluble nonhistone proteins than the normal nuclei. The T-9 and nontransformed nuclei contained similar quantities of histone H4, H3, H2A, and H2B, but the transformed cells contained two dominant subspecies of lysine-rich H1 histone whereas only one histone H1 subcomponent was extracted from the normal nuclei. 79-3599 Lipid Composition of Human Neural Tumors. (Eng) Yates, A. J. (Dept. Pathology, Ohio State Univ., Columbus, OH 43210); Thompson, D. K.; Boesel, C. P.; Albrightson, C.; Hart, R. W. *J Lipid Res* 20(4): 428-436; 1979.

Ganglioside, cholesterol, and phospholipid levels were quantitated in the tissues of 11 human neural tumors and in the cells of two human gliomas cultured in vitro. All tumor tissues contained higher water concentrations but lower total lipid concentrations than either human grey or white matter. In general, they contained less cholesterol, sphingomyelin, and serine glycerophospholipid but more choline glycerophospholipid than white matter. Concentrations of total ganglioside sialic acid were intermediate between grey and white matter. Compared with normal brain, all tumors had greater proportions of the structurally less complex gangliosides and smaller proportions of the more complex gangliosides. This was most marked in the rapidly growing tumors; the better differentiated astrocytomas contained the greatest proportions of complex gangliosides. The cultured tumor cells contained amounts of total lipid and total phospholipid similar to those of their parent tissues. However, the cultures had less cholesterol, sphingomyelin, and total ganglioside than their parent tissues. There were significant amounts of choline and ethanolamine plasmalogens in both cultures and parent tissues. The ganglioside patterns of both cultures were complex, but they contained a greater proportion of structurally simpler gangliosides than their parent tissues. (45 refs)

Subject Index

Abdominal Neoplasms

- Burkitt's Lymphoma
 - Virus, Epstein-Barr, 79-3488
- Toluene-2,4-diamine
 - Carcinogenic Activity, Mouse, 79-3366

Abnormalities

- Kidney Neoplasms
 - Benzoic Acid, 2-(Acetyloxy)-, 79-3361

Acetaldehyde

- Chromosomes
 - Mutagenic Metabolite, 79-3097

Acetaldehyde, Bromo-

- Ethane, 1,2-Dibromo-
 - Carcinogenic Metabolite, 79-3091
- Microsomes, Liver
 - DNA, Binding, 79-3091

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-

- Ames Test
 - S9 Fraction, 79-3319
- DNA Repair
 - Fibroblasts, 79-3310, 79-3428
 - Monocytes, 79-3061
- DNA, Viral
 - Binding, 79-3483
- Fibroblasts
 - Ouabain Resistance, 79-3257
- Guanine
 - DNA Repair, 79-3257
- Lymphoma
 - Mutagenic Activity, 79-3319
- Nucleoside/Nucleotide Adducts
 - Synthesis, 79-3311
- Thymidine Kinase
 - Mutagenic Activity, 79-3319
- Ultraviolet Rays
 - DNA Repair, 79-3428
- Urea, Hydroxy-
 - DNA Repair, 79-3061
- Virus, SV40
 - DNA, Viral, 79-3483
- Xeroderma Pigmentosum
 - DNA Repair, 79-3310, 79-3428

Acetamide, *N*-(Carbamoylmethyl)-2-diazo-

- DNA Fragmentation
 - Alkaline Elution Assay, 79-3239, 79-3307
 - Dose-Response Study, Mouse, 79-3307

Acetamide, *N*-Fluoren-2-yl-

- Adenylosuccinate Lyase/Synthetase
 - Liver, Rat, 79-3362
- Ames Test
 - S9 Fraction, 79-3319
 - Wheat Extracts, 79-3056
- AMP Deaminase
 - Liver, Rat, 79-3362
- Barbituric Acid, 5-Ethyl-5-phenyl-
 - Ames Test, 79-3273
- Cell Differentiation
 - Hepatocarcinogenesis, 79-3305
- Cholanthrene, 3-Methyl-
 - Ames Test, 79-3273
- Dexamethasone

Acetamide, *N*-Fluoren-2-yl- (cont'd)

- DNA Repair, 79-3106
- DNA Repair
 - Hepatocytes, Rat, 79-3106
- DNA Replication
 - Dose-Response Study, 79-3300
 - Liver, Rat, 79-3300
- Epoxide Hydratases
 - Enzymatic Activity, 79-3055
 - Microsomes, Liver, 79-3303, 79-3306
- Glucagon
 - DNA Repair, 79-3106
- Glutamyl Transpeptidase
 - Hepatocarcinogenesis, 79-3305
- Hepatocarcinogenesis
 - Colony Formation, 79-3305
- Hepatoma
 - Cytosine, 5-Methyl-, 79-3053
 - Epoxide Hydratases, 79-3055
 - Methionine Adenosyltransferase, 79-3301, 79-3302
 - Precancerous Conditions, 79-3299
 - RNA, Transfer, Methyltransferases, 79-3301
- Hyperplasia
 - Precancerous Conditions, 79-3299
- Lymphoma
 - Mutagenic Activity, 79-3319
- Mammary Neoplasms, Experimental
 - Cytochrome P-450, 79-3314
 - Disulfide, Bis(diethylthiocarbamoyl)-, 79-3314
 - Organ Culture, 79-3471
 - Virus Activation, 79-3471
- Microsomes, Liver
 - Ames Test, 79-3273
 - Antigens, 79-3299, 79-3306
 - Binding, 79-3306, 79-3314
 - Endoplasmic Reticulum, 79-3299
 - Epoxide Hydratases, 79-3299
- Nucleic Acids
 - Liver, Rat, 79-3309
- Peptides
 - Heme, 79-3303
 - Microsomes, Liver, 79-3303
- Protein Complex
 - Liver, rat, 79-3304
- RNA Polymerase
 - DNA Replication, 79-3300
- RNA, Transfer, Methyltransferases
 - Liver, Rat, 79-3298
- Thymidine Kinase
 - Mutagenic Activity, 79-3319
- Virus, Murine Mammary Tumor
 - Virus Activation, 79-3471
- Wheat Extracts
 - Carcinogenic Metabolite, 79-3056

Acetamide, *N,N'*-Fluorene-2,7-diylbis-

- Ames Test
 - Fluorene, 2-Nitro-, 79-3319
- Lymphoma
 - Mutagenic Activity, 79-3319
- Thymidine Kinase
 - Mutagenic Activity, 79-3319

Acetamide, *N*-(4-(2-Furyl)-2-thiazolyl)-

- Antibody-Dependent Cell Cytotoxicity

- Acetamide, *N*-(4-(2-Furyl)-2-thiazolyl)- (cont'd)**
 Plaque Assay, 79-3297
 Immunity, Cellular
 Chromium Release Assay, 79-3297
- Acetamide, *N*-(4-(5-Nitro-2-furyl)-2-thiazolyl)-**
 Antibody-Dependent Cell Cytotoxicity
 Plaque Assay, 79-3297
 Bladder Neoplasms
 Immunity, Cellular, 79-3297
 Immunity, Cellular
 Chromium Release Assay, 79-3297
 Leukemia
 Carcinogenic Activity, Mouse, 79-3297
 Thymoma
 Carcinogenic Activity, Mouse, 79-3297
- Acetamide, *N*-2-Phenanthryl-**
 DNA Adduct
 Liver, Rat, 79-3309
 Nucleic Acids
 Liver, Rat, 79-3309
- Acetamide, Thio-**
 Adenylosuccinate Lyase/Synthetase
 Liver, Rat, 79-3362
 AMP Deaminase
 Liver, Rat, 79-3362
 RNA
 Adenosine Triphosphatase, 79-3308
 Liver, Rat, 79-3308
- Acetanilide, 3'-Amino-4'-ethoxy-**
 Dose-Response Study
 Carcinogenic Potential, Mouse, Rat, 79-3409
 Thyroid Neoplasms
 Adenocarcinoma, 79-3409
 Carcinogenic Potential, Mouse, Rat, 79-3409
- Acetic Acid, (*N*-Acetyl-*N*-(4-biphenyl)amino) Ester**
 DNA Repair
 Fibroblasts, 79-3310
 Xeroderma Pigmentosum
 DNA Repair, 79-3310
- Acetic Acid, (*N*-Acetyl-*N*-2-phenanthryl)amino) Ester**
 DNA Repair
 Fibroblasts, 79-3310
 Xeroderma Pigmentosum
 DNA Repair, 79-3310
- Acetic Acid, (Ethylenedinitrilo)tetra-**
 Benzenesulfonic Acid
 Oxidative Phosphorylation, 79-3067
- Acetic Acid, Mercapto-**
 Peptides
 Phagocytosis, 79-3208
 12-*O*-Tetradecanoylphorbol-13-acetate
 Phagocytosis, 79-3208
- Acetic Acid, Nitrilotri-**
 Calcium
 Crystalluria, 79-3331
 Excretion, Urine, 79-3331
 Urologic Neoplasms
 Crystalluria, 79-3331
 Dose-Response Study, Rat, 79-3331
- Acetic Acid, (2,4,5-Trichlorophenoxy)-**
 Dibenzo-*p*-dioxin, 2,3,7,8-Tetrachloro-
 Mutagenic Activity, Review, 79-3013
- Acetohydroxamic Acid, *N*-Fluoren-2-yl-**
 Acyltransferases
 DNA Adduct, 79-3320

- Actinomycin D**
 Erythroleukemia
 Cell Adhesion, 79-3200
 Ultraviolet Rays
 Ornithine Decarboxylase, 79-3188
- Acyltransferases**
 Acetohydroxamic Acid, *N*-Fluoren-2-yl-
 DNA Adduct, 79-3320

Acyltransferases (cont'd)

- Amines
 - Metabolism, Rabbit, 79-3317
- Fluoren-2-amine
 - Metabolism, Rabbit, 79-3317
- Hydroxylamine, *N*-Fluoren-2-yl-
 - DNA Adduct, 79-3320
 - Formyl and Propionyl Derivatives, 79-3320

Adenine

- Dimethylamine, *N*-Nitroso-
 - Methylation, 79-3134

Adenine, 3-Methyl-

- Guanidine, 1-Methyl-3-nitro-1-nitroso-
 - DNA Repair, 79-3114
- Methanesulfonic Acid, Methyl Ester
 - DNA Repair, 79-3114
- Xeroderma Pigmentosum
 - DNA Repair, 79-3114

Adenine, *N*-Methyl-*N*-nitroso-

- Lung Neoplasms
 - Carcinogenic Activity, Mouse, 79-3171

Adenine Nucleotides

- Hydrazine
 - Oxidative Phosphorylation, 79-3067
- Sulfate
 - Oxidative Phosphorylation, 79-3067

Adenocarcinoma

- Colonic Neoplasms
 - Hydrazine, 1,2-Dimethyl-, 79-3327
 - Methane, Azoxy-, 79-3327
 - Radon, 79-3446
 - Transplantation, Heterologous, 79-3520
- Esophageal Neoplasms
 - Esophageal Reflux, 79-3535
- Intestinal Neoplasms
 - Hydrazine, 1,2-Dimethyl-, 79-3328
 - Hydrazine, 1,1-Dimethyl-, Hydrochloride, 79-3325
 - Methanol, (Methyl-*ONN*-azoxy)-, Acetate (Ester) 79-3103
 - Pyridine, 2,6-Diamino-3-(phenylazo)-, Monohydrochloride, 79-3404
 - Transplantation, Heterologous, 79-3524
- Keratoses
 - Paraneoplastic Syndrome, 79-3533
- Kidney Neoplasms
 - Chloroform, 79-3082
- Lung Neoplasms
 - Antigens, Neoplasm, 79-3500
 - Cholanthrene, 3-Methyl-, 79-3268
 - Corticotropin, 79-3047, 79-3048
- Mammary Neoplasms, Experimental
 - Acetohydroxamic Acid, *N*-Fluoren-2-yl-, 79-3313
 - Benz(a)anthracene, 7,12-Dimethyl-, 79-3226 79-3231
 - Carcinogenic Potential, Mouse, Rat, 79-3403
 - Chromatids, 79-3352
 - Daunomycin, 4-Demethoxy-, 79-3352
 - Dietary Fats, 79-3332
 - Neoplasm Metastasis, 79-3560
 - Organ Culture, 79-3231
 - Radiation, Ionizing, 79-3066

Fluoren-2-amine

Ames Test, 79-3095

4,4'-Stilbenediol, α,α' -Diethyl-

Ames Test, 79-3335

DNA Adduct, 79-3335

Tryptophan

Ames Test, 79-3095

Microsomes, Liver**Acetaldehyde, Bromo-**

DNA, Binding, 79-3091

Acetamide, N-Fluoren-2-yl-

Ames Test, 79-3273

Antigens, 79-3299, 79-3306

Binding, 79-3306, 79-3314

Endoplasmic Reticulum, 79-3299

Epoxide Hydratases, 79-3299, 79-3303, 79-3306

Peptides, 79-3303

Aflatoxin B1

Ames Test, 79-3273

Heme, 79-3303

Peptides, 79-3303

Barbituric Acid, 5-Ethyl-5-phenyl-

Cytochrome P-450, 79-3273

Epoxide Hydratases, 79-3303

Hydroxylases, 79-3273

Mixed Function Oxidases, 79-3273

Peptides, 79-3303

Benz(a)anthracene, 7,12-Dimethyl-

DNA, Binding, 79-3221

Benzidine

Ames Test, 79-3273

Benzo(a)pyrene

Ames Test, 79-3273

Carcinogenic Metabolite, 79-3264

DNA, Binding, 79-3248

Metabolism, Rat, 79-3248

Benzo(e)pyrene, 9,10-Dihydro-9,10-dihydroxy-

Ames Test, 79-3264

Benzo(e)pyrene, 9,10-Dihydroxy-9,10-oxy-7,8,9,10-tetrahydro-

Carcinogenic Metabolite, 79-3264

Cholanthrene, 3-Methyl-

Cytochrome P-450, 79-3273

Hydroxylases, 79-3273

Mixed Function Oxidases, 79-3273

Cyclophosphamide

Mutagenic Activity, 79-3060

Diallylamine, N-Nitroso-

Allyl Alcohol, 79-3137

Ames Test, 79-3137

Metabolism, Hamster/Rat, 79-3137

Dibenz(a,h)anthracene

Carcinogenic Metabolite, 79-3280

Dibenz(a,h)anthracene, 3,4-Dihydro-3,4-dihydroxy-

Carcinogenic Metabolite, 79-3280

Dibenz(a,h)anthracene, 3,4-Dihydroxy-1,2-epoxy-

Carcinogenic Metabolite, 79-3280

2-Dibenzofuranamine

Carcinogenic Metabolite, 79-3321

N-3-Dibenzofuranamine, Hydroxy-**Microsomes, Liver (cont'd)**

Carcinogenic Metabolite, 79-3321

Diethylamine, N-Nitroso-

DNA, Binding, 79-3165

Dimethylamine, N-Nitroso-

DNA, Alkylation, 79-3134

Nitrogen, 79-3140

Nucleosides, 79-3132

Oxidative Metabolism, 79-3132

Disulfide, Bis(diethylthiocarbamoyl)-

Binding, 79-3314

Ethane, 1,2-Dibromo-

DNA, Binding, 79-3091

Ethanol, 2-Bromo-

DNA, Binding, 79-3091

Fluoren-2-amine

Carcinogenic Metabolite, 79-3321

Guanidine, 1-Methyl-3-nitro-1-nitroso-

Mutagenic Activity, 79-3060

Hydroxylamine, N-Fluoren-2-yl-

Carcinogenic Metabolite, 79-3321

Piperidine, 1-Nitroso-

DNA, Binding, 79-3165

3,6-Pyridazinedione, 1,2-Dihydro-

Mutagenic Activity, 79-3060

Quinoline, 4-Nitro-, 1-Oxide

Mutagenic Activity, 79-3060

Sterigmatocystin

Ames Test, 79-3273

Urea, Methyl Nitroso-

Nitrogen, 79-3140

Vinyl Alcohol

Cells, Cultured, 79-3097

Mutagenic Metabolite, 79-3097

Migration Inhibitory Factor**Asbestosis**

Antinuclear Factors, 79-3076

Streptodornase and Streptokinase, 79-3076

Lung Neoplasms

Antigens, Neoplasms, 79-3500

Horizontal Transmission, 79-3500

Neutrophils, 79-3500

Virus, Murine Mammary Tumor

Macrophages, 79-3473

Mirex**Cholangioma**

Histological Study, Mouse, 79-3085

Hepatoma

Histological Study, Mouse, 79-3085

Mitochondria, Liver**Aflatoxin B1**

Enzyme Activation, 79-3379

Arsenic Acid

Oxidative Phosphorylation, 79-3067

Benzenesulfonic Acid

Oxidative Phosphorylation, 79-3067

Hydrazine

Oxidative Phosphorylation, 79-3067

Sulfate

Oxidative Phosphorylation, 79-3067

Mitomycin C**Chromatids**

Teratogenic Activity, Mouse, 79-3063

Chromosome Aberrations

Teratogenic Activity, Mouse, 79-3063

Mitomycin C (cont'd)

- DNA Repair
 - Monocytes, 79-3061
- Urea, Hydroxy-
 - DNA Repair, 79-3061
- Virus, SV40
 - T-Lymphocytes, 79-3507

Mitosis

- Asbestos

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with The Franklin Institute Research Laboratories for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by The Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index, is \$90.00 U.S., Canada and Mexico and \$120.00 foreign. Individual issues will be charged at \$10.00 to subscribers, \$15.00 each to non-subscribers. Check should be made payable to The Franklin Institute Press.
Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

UNIVERSITY OF CALIFORNIA LIBRARY

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)

REVIEW

- 79-3601 Genetic Control of Carcinogen Metabolism Leading to Individual Differences in Cancer Risk.** (Eng) Nebert, D. W. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD 20014). *Biochimie* 60(9): 1019-1029; 1978.

The characteristics of the P-450-mediated monooxygenases and their coordinated enzymes are reviewed, and genetic differences in this model system in mice are examined. The *Ah* locus controls the induction of at least 20 monooxygenase activities and associated cytochromes P₁-450 and P-448 by polycyclic aromatic compounds. One product of the regulatory *Ah* gene is a cytosolic receptor protein, which has a high affinity for polycyclic aromatic inducers and is defective in nonresponsive mice. Regulation of responsiveness probably involves several alleles at more than one locus, but differences between C57BL/6 (responsive, *Ahb*), and DBA/2 (nonresponsive, *Ahd*) mice can be explained by the difference at the *Ah* locus. Heterozygotes (*Ahb/Ahd*) are responsive, but other genetic crosses can result in the expression of additive inheritance or a situation in which a lack of responsiveness is dominant. Compared with *Ahd/Ahd* mice, *Ahb/Ahb* and *Ahb/Ahd* mice have a high inflammatory response to topical application of 7,12-dimethylbenz(a)anthracene, a high susceptibility to 3-methylcholanthrene (3-MC)- and benzo(a)pyrene (BP)-induced sc sarcomas and 3-MC-induced lung tumors, and an increased resistance to 3-MC- or BP-induced leukemia. The *Ahb* allele is associated in vitro with a high mutation rate in *Salmonella typhimurium* by metabolic activation of several chemical carcinogens. Evidence exists that heritable aryl hydrocarbon hydroxylase inducibility occurs in humans, but experimental difficulties have precluded the possibility of determining whether the induction is controlled by a single gene. (35 refs)

- 79-3602 Detoxification or Toxication? Modification of the Toxicity of Foreign Compounds by Conjugation in the Liver.** (Eng) Mulder, G. J. (Dept. Pharmacology, State Univ. Groningen, Groningen, Netherlands). *Trends Biochem Sci* 4(4): 86-90; 1979.

Studies of the modification of xenobiotic toxicity by conjugation in the liver are reviewed. Generally, conjugation terminates the biological activity of endogenous compounds, such as steroid hormones, but there are exceptions. Studies with estrone sulfate suggest that conjugation of certain hormones prevents their elimination and may result in transport forms of these hormones that are specifically labeled for uptake in target cells. Benzo(a)pyrene is converted by microsomal monooxygenases into chemically reactive products that are responsible for

liver cancer. Sulfation of N-hydroxy-2-acetylaminofluorene (N-hydroxy-2-AAF) leads to an extremely reactive species that has been implicated in the carcinogenic action of this compound. N-Hydroxy-2-aminofluorene, N-acetoxy-2-aminofluorene, and, possibly, N-acetoxy-2-acetylaminofluorene are formed in vivo through enzymatic transacetylation in the liver. These compounds may also be involved in the carcinogenicity of N-hydroxy-2-AAF. Evidence for the generation of a reactive intermediate by drug-metabolizing enzymes rests on two indirect assays: covalent binding of a compound to macromolecules and the *Salmonella typhimurium* mutagenicity test. 1,2-dichloroethane is chemically activated to a more potent mutagen by glutathione conjugation. These findings may lead to a reevaluation of conjugation in the toxification of xenobiotics and in the intermediary metabolism of endogenous compounds. (21 refs)

- 79-3603 Tobacco and Health: A Societal Challenge.** (Eng) Wynder, E. L. (Naylor Dana Inst. Disease Prevention, Valhalla, NY 10595); Hoffmann, D. *N Engl J Med* 300(16): 894-903; 1979.

Three aspects of the effort to prevent or control health problems caused by smoking are reviewed: (1) youth antismoking programs; (2) smoking-cessation programs; and (3) development of a less-harmful cigarette. Various known and suspected tumorigenic agents have been identified in tobacco smoke. Numerous cigarettes with <10 mg tar and lower levels of nicotine are on the market, but their acceptance depends on the increased use of flavoring agents derived from tobacco. Assuming that all available safety techniques are used and that none of the flavor additives induce additional toxic effects, some max levels for certain smoke constituents in a less-harmful cigarette are proposed: tar, 8 mg; nicotine, 0.6 mg; carbon monoxide, 8 mg; hydrogen cyanide, 100 µg; and benzo(a)pyrene, 8 nanograms. (91 refs)

- 79-3604 Environmental Cancer: On the Causes of the Main Human Cancers.** (Eng) Weisburger, J. H. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY 10595). *Tex Rep Biol Med* 37: 1-20; 1978.

Causes of the main human cancers are reviewed briefly. Occupationally incurred cancer arises in individuals exposed at work to varied carcinogenic chemicals, and it develops cancer at a site that is determined by the nature of the carcinogen. In the context of the total incidence of

REVIEW

cancer in the US, occupational cancer assumes a minor quantitative role. Nonetheless, provided proper plant design and hygienic measures are developed, these cancers are totally preventable. Most of the remaining human cancers in the US such as cancer of the respiratory and digestive tracts (including the stomach and large bowel) and of the endocrine-sensitive organs (including the breast, prostate, ovary, and endometrium), are related to lifestyle; namely, cigarette smoking and diet. The mechanism whereby lifestyle translates to certain of these diseases is presented. (66 refs)

- 79-3605 Some Monomers, Plastics and Synthetic Elastomers, and Acrolein.** (Eng) IARC Working Group (Unit Chemical Carcinogenesis, IARC, Lyon, France). *IARC Monogr Eval Carcinog Risk Chem* 19: 1-513; 1979.

Monographs published by the International Agency for Research on Cancer (IARC) summarized evidence on the carcinogenic risk of individual chemicals to humans and other relevant information. The analyses are intended to assist national and international authorities in formulating decisions concerning preventive measures. The chemicals selected for evaluation are those to which humans are exposed and for which there is some experimental evidence of carcinogenicity. Using data collected from appropriate tests in animals, it is possible to extrapolate to estimate possible human risk. The individual monographs contain chemical and physical data on each compound; its production, use, occurrence, and means of analysis; biological data relevant to the evaluation of carcinogenic risk in humans; and the critical analyses of the data by the IARC Working Groups. The data analyzed include those from carcinogenicity studies in animals, lethality, toxicity, and metabolism studies; studies and observations of embryotoxicity and teratogenicity; and indirect mutagenicity and other short-term tests. - 79-3606 Environmental Cancer: Animal Studies and Assay Procedures.** (Eng) Griffin, A. C. (Dept. Biochemistry, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Tex Rep Biol Med* 37: 45-49; 1978.

In developing an animal testing program for determining the carcinogenicity of environmental chemicals, species, strain, age, sex, number, maintenance, and cost of the test animals; dosage and mode and duration of administration of the test chemical; and length of the study must be considered. Evaluation of the findings should include gross evaluations of animals, histopathological studies of tissues and organs, data evaluation and statistical aspects, extrapolation of data to humans, and final evaluations and recommendations involving governmental agencies, labor, and industry. - 79-3607 How Do We Know What Causes Cancer?** (Eng) Shaw, C. R. (Dept. Biology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030); Leal, N. *Tex Rep Biol Med* 37: 21-25; 1978.

Tests to determine whether a chemical will produce genotoxic or mutagenic effects involve humans, other animals, or bacteria. The most widely used bacterial test is the Ames *Salmonella typhimurium* mutagenicity assay. One problem with this test arises from the fact that most chemicals are not actively toxic in the forms in which they are taken into the body. Other problems involve genetic variations in the ability to metabolize chemicals, variations in the levels of enzymes involved in DNA repair, and individual differences in the degree of immunosurveillance. - 79-3608 The "Natural" Food Myth.** (Eng) Rhodes, M. E. (Food Lab., Div. Chemistry, Dept. Agriculture and Consumer Services, Tallahassee, FL). *Sciences* 19(5): 11-30; 1979.

Consuming only foods labeled natural does not necessarily eliminate poisons from food, as there are many natural poisons in food. However, the concentrations of these natural poisons are so low that a huge amount would have to be consumed over a long period of time for the toxic effect to become apparent. Food additives such as nitrates and nitrites, as well as sodium benzoate, occur naturally in leafy vegetables and cranberries, respectively. Some natural components of food, such as aflatoxin, which produces liver cancer in laboratory animals, may actually be harmful. (no refs)

- 79-3609 Iatrogenic Complications of Dermatologic Therapy.** *Primum non Nocere.* (Eng) McMeekin, T. O. (300 White Spruce Blvd., Rochester, NY 14623); Moschella, S. L. *Med Clin North Am* 63(2): 441-452; 1979.

Adverse reactions to systemic and topical drugs and to physical modalities in the treatment of skin disease are reviewed. Radiotherapy and systemic azathioprine therapy, the latter of which is used to treat pemphigus vulgaris, may be complicated by the development of malignant disease. The development of keratoses in chronic radiation dermatitis may herald malignant degeneration. There is also an association between external radiation and delayed neoplastic changes in the thyroid. Hazards are also associated with dermatologic use of the cytostatic drugs podophyllin and γ -benzene hexachloride. (98 refs)
